CANCER TESTS AND TREATMENT

By P N PANTON M.B.

DIRECTOR OF THE CLINICAL AND BUREAU OF THE LONDON HOSPITAL

SOARINGLY a year passes without the outcome of some new cancer test or cancer findings have been a reputable source and widely from the straining for specificity or effectiveness just to make two types a number of such claims have the one a general test various workers in the London tests will give a history and it seems worth while to state the results of their investigations. The following are some criteria by which the particular should be judged as a practical method.

For each test investigated every have been tested and worked when possible in order to ensure accuracy of the method and in the hands of a reliable technician from the author himself has met. When special apparatus has been obtained in the test derived.

For most of the tests it has been claimed that a very high percentage of results is possible, and this has been demonstrated when the clinical diagnosis is concealed from the technician by the use of a placebo. But this precaution of misdirection may give an entirely false idea of the value of a test since it appears that there is no coordination between clinician and laborer by which the clinical diagnosis is altered in the test. The conditions insisted at the London Hospital are given in the form of the test most recently investigated, round Kaminer reaction. Many cancer tests are based upon theories concerning the nature and treatment of cancer and refer to some of these treatments. In none of these tests is not associated with a test is described.

Abderhalden

Abderhalden first described in 1912 and in the following two years papers almost all of which were confirmed in the German medical press. Originally a test for pregnancy it was later claimed as a means of diagnosing disease of any organ and particularly as a test for cancer. The test depended upon the presence of ferriprussic acid for any products abnormally present in placenta in pregnancy for breast cancer and so on. The presence of the ferriprussic acid was detected both by dialysis after mixing the substrate of the tissue with the serum in a dialyzing tube impermeable to albumin, examining the dialysate for peptone and by examining the serum films were investigated by Dr J O Gavronsky, laboratory specialist for the purpose and published in Prof Abderhalden's laboratory. The results of an investigation of 121 cases published by Gavronsky (1916). It was found that there was no specificity in these ferriprussic acid tests. In all of the patients rarely any

STUDIES IN THE

SERUM TREATMENT OF LOBAR PNEUMONIA

involved in sodium vanadate serum therapy in lobar pneumonia. Ultra violet absorption in the protody have been based on tuberculosis were also said to show a so that observations absorption curve. Dr Bendien a gladd to the accumulation of a special knowledge of aid help to form the metry was greatly handicapped by the figures in this given to his work by the lay press in Holl study of 800 cases this country. The test was investigated a period of five laboratories by Prof. J B Varrack Dr F Camph Smith, and Dr E R Holiday and in Holland with the help of Dr Bendien. The investigation was confined to the reliability of the spectrophotometric observations. It was found almost at once that the yellow solutions of protein-sodium vanadate in sodium bicarbonate rapidly faded and finally became colourless on exposure to light and that the two absorption curves obtained before and after fading corresponded respectively to the tuberculosis and the cancer curve of Bendien. The same result could be obtained from the sera of cancerous and non-cancerous subjects and a report to this effect on the investigation of 40 cases has not been contradicted in any published work (Smith, Holiday and Mack 1931). The test and a form of treatment controlled by it is still practised but the test mainly relied upon is the sodium vanadate precipitation and not the absorption curve.

Schubert Dannmeyer Test

This test was first brought to my notice by Dr A J Ormston and was investigated in these laboratories by Dr Holiday and Dr Campbell Smith after Dr Holiday had spent sufficient time in Hamburg to acquire the technique. The test was developed from the hypothesis that the lipin fraction of cancer serum is altered. Schubert claimed to be able to detect this alteration by the difference of certain electrical properties between a lipin extract of cancer serum and that from normal serum. The method consisted of preparing a suitable extract with hexane and measuring the rate of discharge of a quantity of electricity through the extract. It was claimed that in extracts from normal sera the discharge was complete whereas in cancer serum extracts a certain charge always remained residual potential. The test was examined in two series of cases and a report published in 1935 (Holiday and Smith). The authors concluded that the method as it stands seems to us to be of no clinical value as a diagnostic test for cancer.

The King Cancer Treatment

A treatment resulting from the work of Dr A C King in Kenya was investigated at the request of the British Empire Cancer Campaign. Dr King adopted the theory that extracts of certain organs injected into the blood stream might cause necrosis

 apparatus since the limits of error of the
 methods exceed the minute differences found
 in disease

Working in the laboratories of Prof. D. T. Harris,
 Dr Fuchs carried out the test in two series of cases
 selected by me on the same condition as those
 prescribed for the Freund Kammer reactions. The
 first series consisted of 44 cases, and of these the
 results were correct in 25 and wrong in 19, both
 false negatives and false positives occurring. The
 series was discontinued in order that Dr Fuchs
 might control his reagents with known normal and
 cancer sera. A second short series was then begun
 and of 13 cases the test result would appear to have no
 these findings the test would appear to have no
 value, but it is proper to add that Dr Fuchs believes
 that some fault must have been present in one of
 the reagents and he proposes to repeat the test in a
 future series

Freund Tests and Treatment

Prof Freund, working now in the Pearson Insti-
 tute in Vienna, has during the last fifty years
 elaborated a theory of the causation of cancer upon
 which diagnostic tests and treatments of cancer are
 based. He believes that a substance produced
 mainly by the thymus and able to destroy cancer
 cells is present in childhood and that as age advances
 this "normal substance" diminishes. Also that
 foods rich in animal fats effect a change in the
 intestinal flora so that fats are digested and the
 stances produced which protect cancer cells from sub-
 by the normal substance. Evidence for these state-
 ments is offered in the results of the diagnostic tests
 The original Freund Kammer test was based on the
 claims that normal sera lysed some 60 per cent of
 cancer cells in suspension and sera of cancer subjects
 a smaller percentage, also that cancer sera added to
 normal sera inhibited the lytic action of the latter
 As further evidence of Freund's hypothesis it is now
 said that an abnormal coliform bacillus resistant to
 1 per cent hydrochloric acid can be isolated from
 the faeces of cancer subjects, that this bacillus grown
 in milk rich in cream produces an other extractable
 substance having antilytic properties similar to the
 the bacillus is agglutinated by the sera of cancer
 subjects but not by normal sera. A further claim,
 which appears inconsistent with recognised immuno-
 logical processes, is that this cancer protective

 8—or approximately 14 per cent. gave indefinite results.
 23 correct
 25 incorrect

Of the indefinite tests the percentage is 45 correct and 55 incorrect. Since each result depends upon a summing up of several tests it is difficult to assess the accuracy and the distribution of correct and incorrect results suggests that it is the outcome of chance. Certainly these tests on these findings have no diagnostic value and differ widely from the standard claimed for them. It is just to make two observations about these results: the one a general statement that very few diagnostic tests will give a 90 per cent accuracy in such conditions as were imposed here and the other on a matter peculiar to these reactions, the single result of which is derived from four or five different tests. If one or two of the tests have little value they will depress the value of the other tests and there was in this series evidence of this since the peculiar agglutination reaction considered alone in the last 68 cases of the series gave 71 per cent of correct results. Even this percentage however can scarcely be considered satisfactory.

Discussion

The problems of the early diagnosis and the treatment of cancer are so important that one cannot reject claims to solve these problems even if the theories underlying them do not seem inherently probable. There is the further reason for an impartial examination that both tests and treatments coming from a reputable source are apt to be exploited by less scrupulous persons. All the tests described in this communication some of which are of considerable antiquity are still widely used. In some cases important modifications have been made in the test and these alterations make the final assessment of the diagnostic value always open to criticism. The tests first described here those of Abderhalden are of great theoretical interest and as first described are to be entirely specific yet in spite of these constant changes were made in the technique of the changes were mainly in the direction of further complexity so that one can only conclude that the unproved claims were imperfectly controlled. A much more important underlying cause for the exaggeration of the claims for a diagnostic test in particular for the usual divorcement of the wards of a hospital staff from direct contact with tests and treatment in hospital. Clinical control of tests and treatment have been in general lacking and in some cases impossible. The view of the importance of these matters and the interest taken in them by the lay public it would most seem advisable that some official body should be responsible for assessing the value of all cancer and cancer cures as soon as they are published and with the knowledge that exploitation of ignorance and with the knowledge that exploitation was contemplated that certain of these tests were investigated here.

The examination of these diagnostic methods has involved much time and often highly technical knowledge of chemistry and physics for all of which I am indebted to my colleagues at the London Hospital.

The published results of serum therapy in lobar pneumonia in this country have been based on comparatively small numbers so that observations on yet another modest series will add to the accumulating knowledge of the subject and help to form the basis of a critical valuation. The figures in this series have been collected from a study of 800 cases arising in the city of Salford over a period of five years. Of these cases 112 were treated with anti pneumococcus serum during the past two and a half years.

It is very difficult to obtain an estimate of the incidence and fatality rates of typed lobar pneumonia on any large scale but the fifteenth annual report of the Ministry of Health shows that 60 000 cases of pneumonia in all forms were notified in 1933-34 the fatality rate being 50 per cent. In the city of Salford with a population of 230 000 the number of cases notified in 1935 was 475 of which approximately 53 per cent died. While no accurate information can be gained from these figures it is evident that the fatality rate is high and that it is important to investigate any form of treatment which might reduce the high fatality rate of a prevalent infectious disease. In this series the fatality rate in 688 cases of lobar pneumonia of all types (not treated with serum) was 24 per cent. As analysis (into age groups) will show this figure is misleading and does not indicate the true state of affairs.

TABLE I

The classification of lobar pneumonia according to the type of the infecting pneumococcus shows that the frequency of the serological types varies in different countries. In Britain Types I, II and III are commonly differentiated the remaining types, numbering 23 being described as belonging to Group IV. The figures given in Table I show the

ence in Hope Hospital, Salford. The average incidence of Type I pneumonia in that given for other localities in Britain, workers were the first to point out that the incidence of pneumococci varies with the type of the pneumonia problem is illustrated by the analysis of 688 cases of lobar pneumonia not treated with serum (Table II). The importance of age in prognosis has long been known to clinicians. Advancing years render the outlook more grave. The striking effect of age on fatality-rate is easily seen in Table III. It shows

TABLE III
Incidence and fatality rates, in age groups and according to Type, in 688 cases of lobar pneumonia not treated with serum

Age group	Type I		Type II		Type III		Group IV	
	Inc	Fa	Inc	Fa	Inc	Fa	Inc	Fa
16-19	14% (46)	4% (2)	15% (23)	17% (4)	—	—	18% (35)	8% (2)

In Tables I and III and the following tables the figures in parentheses denote the actual numbers of cases

that the fatality rate increases steadily with age irrespective of type and that above the age of 40 lobar pneumonia is especially fatal

From Tables I, II, and III it will be seen also that about 75 per cent of cases of lobar pneumonia belong to Types I and II, and that the fatality rate for these types over the age of 40 is much higher than 24 per cent. In this paper attention is drawn particularly to the treatment of Type I and Type II lobar pneumonia with anti pneumococcus serum

In considering the results of serum therapy in lobar pneumonia it is imperative to recognise the influence of age on fatality. For this reason the results are arranged in tabular form in age groups. Two other factors must also be remembered (a) the day on which serum treatment is commenced, and (b) the dose of serum employed. In America it is held that treatment should be begun early, if possible in the first three days. For the purpose of this investigation all patients between the ages of 16 and 60 were treated whenever their initial dose of serum could be given before the end of the third day of illness. The serum employed were Lister Institute anti pneumococcus serum Type I concentrated and serum Type II concentrated and non serum treated cases. The results (serum-treated and non serum treated cases) are set out in Table IV. The two sets of figures are comparable in that they are derived from the same case sequence, being differentiated only by the fact that the cases treated without serum were

admitted to hospital after the third day of illness. It was felt to be justifiable and scientifically sound to use as controls those cases admitted to hospital after the third day of illness for the following reason. An analysis of 457 cases of typed lobar pneumonia admitted to hospital during the three years ending

TABLE IV

Exp fa = expected fatality. See text

Sept 30th, 1934 (before serum was used) showed that the fatality-rate was not influenced by the day of illness on admission to hospital. This is shown in Table V

The fatality-rates indicate that it is not the grave disease in patients who are admitted to hospital late in the day of illness. If clinical judgment is any guide patients admitted after the third day of illness are not necessarily more ill than those admitted earlier. Grave illness is more often than not a reason for non-removal to hospital

TABLE V

Day of illness on admission	Cases	Deaths	Fatality per cent	Day of illness on admission	Cases	Deaths	Fatality per cent
1st	30	—	—	6th	41	—	—
2nd	70	9	30.0	7th	28	10	24.4
3rd	117	21	26.6	8th	7	7	25.0
4th	88	32	27.3	9th	2	2	28.6
5th	65	27	30.6		1	1	50.0
		21	32.3				

Of the cases set out in Table IV the average day of illness on admission to hospital of serum treated cases was 2.3 days while that of cases treated without serum was 4.9 days. It will be seen that the patients treated without serum did not include a preponderant number who were admitted late in the disease. In fact no patients admitted after the ninth day of illness are included in the control series.

The general nursing care and the use of oxygen when necessary are common to both groups. On the whole the results are highly favourable to serum therapy, especially in patients below the age of 40. The figures are small and must be interpreted with reserve particularly as it has been shown that there is a preponderance of serum treated cases under the age of 40 where the fatality rate in any case is lower. Further in the age group 16-19 Type II

serum treated series the fatality rate is actually higher than in the same age group without serum. A similar unexpected finding is seen in the age-group 0-40 in the Type I series. It may be mentioned that of the three deaths in the age-group 40-49 above one case had been under treatment for pulmonary tuberculosis for seven years and tubercle bacilli were present with pneumococci in the sputum while another case at post-mortem examination was found to have renal tuberculosis. In the age-group 50-59 Type I serum treated series the only death recorded occurred in a pregnant patient with a bleeding placenta praevia. The one and only death in the age-group 16-10 Type II serum treated cases occurred in a youth of 18 with pneumonia of both lower lobes associated with slight jaundice and a daily positive blood culture. The inclusion of such cases with an already grave prognosis may explain the unexpected results when the numbers are so small.

AGGLUTININS IN LOBAR PNEUMONIA

The appearance of agglutinins in the blood-serum is recognised by some authorities as an indication of recovery while others state that their appearance does not exclude the possibility of relapse or complications. A study of this question in Salford in 84 cases of lobar pneumonia which were not treated with serum showed that agglutinins were readily recognised in the blood-serum before dying, or immediately after the crisis in all but 12 recovered cases. Failure to detect agglutinins in all recovered cases has also been noted by others^{1,2} and it has been suggested that although they are absent a protective antibody is present. It is well known that experimental immunisation does not always lead to the production of antibodies although a high degree of resistance is reached. A similar absence of agglutinins may follow an acute Sonne dysentery infection in some persons during an epidemic though in the majority agglutinins are present.

In this study of 84 cases 26 were fatal. Agglutinins were absent in 21 of these fatal cases and present in 5. The presence of agglutinins in the 5 fatal cases suggests that there might have coexisted with the pneumococcal infection some other previous pathological process which was aggravated by the superimposed acute infection. This was found to be the case in 4 of the fatal cases. There was only one in which death could be attributed to the pneumococcal infection alone.

DOSAGE OF SERUM

The regulation of the dosage of serum for therapeutic purposes by the microscopic detection of passive agglutinins in the patient's blood-serum was first used by Sabin,¹¹ and is now a routine procedure in certain New York hospitals. Some workers¹² however do not think the test reliable. In Salford it has been used in all serum treated cases. At first it was the practice to inject 20 000 units anti pneumococcus serum intravenously as an initial dose immediately the type was known but so many cases required at least one further dose that it was very soon decided to give an initial dose of 40 000 units. At night if there was delay in typing 20 000 units of each of Type I and Type II serum were given as a first dose. Thereafter further dosage was determined by the result of the agglutination reaction from day to day. This subject has been more fully dealt with elsewhere.¹³ If agglutination was absent a further dose of 40 000 homologous units was given or if the reaction was poor or moderate 20 000 units were administered. This procedure was repeated

daily until a persistent good reaction was obtained. Serum was then withheld although clinically the patient might not appear to have recovered. A persistent good reaction was obtained in some cases after 20 000 or 40 000 units but others required more. In a few patients the reaction was poor even after the injection of 160 000 units, and as many as 200 000 units have been necessary. The agglutination reaction does not appear to depend on the amount of serum administered but on the amount of excess antibody (passive or active) free in the blood serum. The average total dosage per recovered patient is shown in Table VI. It might be expected

TABLE VI

Age-group	Average total dosage per recovered patient	
	Type I	Type II
16-10	Units. 32,000	Units 35,000
0-9	49 000	60 000
30-39	58 000	8,000
40-49	87 000	56,000
50-59	80 000	55 000
16-60	60 400	56,800

that the total amount of serum per patient would increase with age because of the diminishing power to produce active antibody in older patients. The Table does not support this expectation. The cost of serum to the hospital is on an average 23 per patient—a very modest sum.

EFFECT OF SERUM

Apart from reducing the fatality rate serum therapy shortens the duration of the acute illness as is well shown in Table VII. The termination of the acute illness has been recognised as the first period of 24 hours during which the temperature does not exceed 99 F. The figures in Table VII are in

TABLE VII

Duration of the acute illness in recovered cases treated (a) with serum and (b) without serum

Age-group	With serum		Without serum	
	Type I	Type II	Type I	Type II
Average days				
16-10	5.1 (10)	6.4 (11)	8.5 (13)	6.5 (6)
20-29	5.5 (1)	5.8 (11)	8.6 (23)	7.0 (7)
30-39	6.4 (2)	1 (9)	7.7 (16)	8.3 (7)
40-49	6.5 (9)	4.6 (6)	9.6 (13)	8.4 (5)
50-59	4.8 (5)	6.0 (3)	5 (11)	7.5 (6)
16-60	5 (61)	5.5 (60)	8.3 (61)	(21)

close agreement with those reported by the Therapeutic Trials Committee of the Medical Research Council.¹⁴ It will be noticed that age does not appear to have any influence on the duration of the acute

illness. In some, crisis has been observed immediately after the first injection of serum. The importance of reducing by 2-3 days the duration of a toxic and distressing illness is obvious. Increasing discomfort is avoided and the patient's general strength conserved.

SERUM ANAPHYLAXIS

Serum reactions of a mild type were observed in 12 cases between the eighth and fifteenth day after the first dose of serum. An erythematous rash appeared in 7 cases, arthritis in 4, and in 1 case there was a feeling of general malaise. These anaphylactic symptoms lasted only from one to two days. It is not possible to incriminate any particular serum as 10 of the patients had received an initial dose of both Type I and Type II sera, one had Type I only and another Type II serum alone. Serum reactions are no more common in the treatment of lobar pneumonia than in any other disease treated with serum.

COMPLICATIONS

Table VIII is a list of the complications observed

culture positive cases than amongst the blood culture negative cases. The prognostic significance of bacteræmia is apparently the same whether the infecting pneumococcus belongs to Type I or Type II. A positive blood culture does not seem to be more common in Type I cases than in Type II cases. This tendency is not in keeping with the idea of the greater "invasiveness" of Type I pneumococci. In the groups of patients treated with serum there were 5 deaths amongst those having positive blood cultures. In all these cases bacteræmia persisted after the third day of illness. The small numbers make it impossible to come to any decision as to the effect of serum on bacteræmia. It is meantime a matter for speculation as to whether the successful use of serum by shortening the period of the acute illness prevents a bacteræmia which would arise if the acute period lasted longer.

GENERAL REMARKS

The numerous factors known to influence the fatality of lobar pneumonia require the investigation

TABLE VIII

In the serum treated groups of cases complications appear to be less numerous and less varied in character than in the series treated without serum. Empyema may be present as early as the fifth day of illness.

BACTERÆMIA

At the commencement of the investigation in Salford it was the practice to take blood for culture on the day of admission and again at intervals of two to three days during the acute illness. It was soon found that any information thus obtained was not reliable. The figures set out in Tables IX and X and XI and XII have been derived from patients from whom blood for culture was taken daily during the acute illness. It must be pointed out at once that the figures are small. They are merely placed on record and a note made of the possible inferences. With increase in age bacteræmia seems to be more common and the prognosis more grave. Irrespective of age the fatality rate is always much higher amongst the blood

of a large number of cases and many epidemics. As already indicated we consider the number of cases in this study small therefore we hesitate to make dogmatic statements. Nevertheless we feel that the results obtained are very encouraging and we are convinced that serum therapy was a real help in the cases treated. Although we have no wide experience of the value of serum treatment when it is commenced later than the third day of illness, it is logical to demand for anti pneumococcus serum the same conditions as are laid down for the use of other sera. We regret the fact that a large number of patients arrive in hospital at a late stage of the illness. Many are sent in with a diagnosis of influenza pneumonia, a disease which, in Salford at least, is rare. It is recognised that the diagnosis of lobar pneumonia on the first or second day may be difficult in a few cases but by the third day the signs are usually well defined. Certain of our first- and second day cases have been accurately diagnosed on the history alone.

We follow in the footsteps of the late Dr. J. H. S. ...

We think that in the presence of some or all of the following symptoms or signs—rigor vomiting pain in the chest dyspnoea and cough—it is justifiable to administer anti pneumococcus serum early and make the diagnosis later as is often done with diphtheria antitoxin and antimeningococcal serum. A polyvalent serum should be used until the type can be determined. Seventy five per cent of our cases belonged to Types I and II. Bacteriological typing is an essential procedure. It is now both simple and rapid and in the majority of instances a correct diagnosis can be made within 30 minutes. Test sera are freely available in the open market. Typing should present no difficulty in a well-equipped hospital or municipal laboratory and in view of the serious nature of lobar pneumonia we are strongly of the opinion that local authorities should make provision for the typing of pneumococci in order to assist smaller hospitals and general practitioners. Although we have used the agglutination reaction to determine the amount of serum necessary in treatment yet we do not consider it essential in the routine clinical use of serum. It has helped to economise serum.

The use of serum in lobar pneumonia has given rise to a certain amount of destructive criticism. It seems to us that such criticism is unwise while the method is still under trial, especially as it is the only scientific means of treatment available. We maintain that many accepted lines of therapeutic intervention in serum therapy for lobar pneumonia by many workers in America and in this country would probably emerge from the ordeal somewhat discredited. There is a real danger of premature crit-

cism discouraging the further production of serum before an extensive inquiry into its use has been completed. The treatment is not difficult or trouble some. The intravenous route of serum administration is easy and painless and anaphylactic phenomena are no more frequent than in any other disease so treated. The cost of serum is by no means high.

Finally we submit that the results recorded from our study of a comparatively small number of cases encourage continued investigation into the treatment of lobar pneumonia with anti pneumococcus serum.

It is our pleasant duty to thank Dr G J Crawford pathologist to the city of Salford for much help and advice and the assistant medical officers and nursing staff of Hope Hospital for ready and cheerful co-operation. To Dr J D Giles medical superintendent Dr H Osborne medical officer of health, and the health committee we are indebted for making this work possible. And finally to Dr G F Petrie of the Lister Institute and Dr R A O'Brien of Messrs Burroughs Wellcome and Co. we offer our best thanks for supplying serum.

ANCYLOSTOMA ANÆMIA

By M. MAHFOUZ FIKRI, M.B., B.Sc.,

D.T.M. & H. Lond

LECTURER IN CLINICAL PATHOLOGY IN THE UNIVERSITY,
CAIRO AND

PAUL GHALIOUNGUI, M.D., M.R.C.P. Lond

MEDICAL TUTOR IN THE UNIVERSITY

I—THE BLOOD VOLUME

In anæmia due to ancylostoma infestation the total blood volume has been stated to be increased to such an extent that although the number of red cells per cmm is greatly reduced, the total oxygen capacity of the circulating blood is normal (Boycott and Haldane 1903, Boycott 1911). In 1934 Prof. A. G. Biggam and one of us (P. G.) suggested that this finding could explain the mildness of the symptoms these patients complain of, relative to the degree of apparent anæmia, the idea being that the blood was only in some way diluted, the total oxygen bearing capacity being unimpaired.

METHOD

Before further pursuing the implication of this, we thought of confirming these results. Our method of estimating the blood volume was however a different one. It is based on the intravenous administration of congo red, a dye which is non-toxic and only slowly excreted, and is described in detail by Todd and Sanford (1931) after Keith, Rowntree, and Geraghty (1915) and Rowntree and Brown (1929). The congo-red we employed was Schering Kahlbaum's indicator (p. g. VI) which was proved to be non-toxic by intravenous injection into a dog.

The number of cases to which the method was applied was limited by the rarity of pure ancylostoma infestation. Associated helminthiasis, or dysentery, or pellagra were rigidly excluded by careful clinical, pathological and sigmoidoscopic examinations. The subjects were asked to attend the laboratory at 8.30 A.M. without breakfast and were then kept lying warm and recumbent before the actual performance of the test. The solution of the dye was prepared fresh on the day of the determination, all syringes and needles were carefully dry sterilised, and after the subject was weighed the amount of dye for injection was calculated. Blood was withdrawn from one arm into oxalated graduated centrifuge tubes to obtain the hematocrit reading and the plasma colour. The solution of the dye was then injected very slowly,

the operation taking one minute, and 3 mins exactly after the middle of this period blood was withdrawn from the other arm into another oxalated graduated centrifuge tube. Calculation of the result was done exactly as originally described.

In all, 20 cases of ancylostoma anæmia were examined. The accompanying Chart shows the results, the numbers inset in the stippled areas representing plasma volume per 100 ccm of blood. We also examined 5 normal cases to check our results and to find out the average normal for our class of patients. The results are similarly recorded in chart and compare with results of other authors. Two cases infected with ancylostoma but not anæmic were also examined. Their blood volumes were 102 and 91 ccm per kg body weight respectively—i.e. slightly higher than the anæmic cases. They were excluded from this series.

RESULTS

(1) The average total blood volume of the ancylostoma cases is 79.5 ccm. per kg of body weight—i.e., about or slightly below the normal (89 ccm.)

(2) The average plasma volume in ancylostoma anæmia is 62.6 per kg body weight—i.e., slightly higher than the normal (54 ccm.)

(3) The diminution in total blood volume in ancylostoma can be accounted for entirely by the diminution in total volume of red cells.

(4) Taken as percentage—

	Normal.	Ancylostoma
Plasma (%)	60	78.6
Red cells (%)	40	21.4

(5) The total blood volume bears no relation to the degree of anæmia as indicated by hæmoglobin percentage, but with increasing degrees of anæmia the percentage of plasma increases and the corpuscular volume diminishes.

CONCLUSION

No increase in total blood volume was found in anæmia due to infestation with ancylostoma, on the contrary there may be a tendency to diminution.

II—GLUCOSE TOLERANCE CURVES

In attempts to explain the causation of ancylostoma anæmia deficient intestinal absorption has been postulated as one of the contributory factors. Many authors hold different views, regarding hæmorrhage or a possible toxic factor as being the most important cause. In the absence of any balance experiments

deficiency of absorption would be difficult to prove, and owing to the difficult and unrepeatable character of these help in the interpretation of these results, we thought logical to approach the problem in a different way—by investigating the sera of infected subjects and patients.

The patients were all of pure ancylostoma infestation, those harbouring other intestinal parasites or suffering from dysentery, diarrhoea, or fever, being rigidly excluded. This explains why we could investigate only 18 cases in three years.

The blood volume in 20 cases of ancylostoma anæmia. The upright columns indicate the volume in ccm per kg of body weight. The figures in the stippled areas show the proportion of plasma—i.e. ccm per 100 ccm of blood. A = average of the 20 cases B = recognised normal (other authors) C = average of 5 normal subjects

Before the actual test the subjects were kept on the standard hospital diet for about a week, and then first thing in the morning 15 grammes of glucose per kilogramme of body weight was given in 300 c.c. of water. The venous blood-sugar was estimated by Folin and Wu's colorimetric method before the patient drank the glucose solution and then every quarter of an hour subsequently in the first few cases. Later it was considered that fifteen minute intervals for the first hour and then half hourly intervals were satisfactory. From a long experience we know that the average glucose tolerance curve of our class of patient does not differ materially from accepted standards. In the evaluation of the results we classified them as follows —

Normal curves: blood-sugar rising 40 mg. per 100 c.c. or more above fasting level reaching a maximum in less than an hour and falling to less than 20 mg. above fasting level in 2 hours.

Low curves: maximum rise never reaching 40 mg. per 100 c.c. above fasting level.

Delayed rise: continuing to rise longer than 45 min.

Delayed fall: after 2 hours still 20 mg. or more above fasting level.

The actual figures are shown in the Table

Case no	Remarks.	Fasting blood-sugar	Blood-sugar estimations.										Maximum rise above fasting level	Rise after hours
			Time (hours)											
			1/4	1/2	1	1 1/4	1 1/2	2	2 1/4	2 1/2	3	Degree

Figures in Italics show the maximum rise in each case
+ Figures considered abnormal are given in Italics

P + = Enlarged parotid, a frequent feature in anæmia in Egypt
Iv = Glucose administered intravenously

RESULTS

Curves were normal in 6 cases. 8 showed a low curve, 4 a delayed fall and 9 a delayed rise.

These abnormalities were usually present together only 3 cases showing any one of them as an isolated feature.

Glucose-tolerance curves in 18 cases of ancylostoma anemia. Cases 9 and 12-18 show curves also after intravenous injection of glucose.

The 18 cases may be divided as follows —

Normal	6
Low curve + delayed rise	6
Low curve + delayed fall	1
Delayed rise + delayed fall	1
Low curve	1
Delayed rise	1
Delayed fall	1
Total	18

GLUCOSE TOLERANCE AFTER INTRAVENOUS INJECTION

In 8 of the 18 cases the curves were also determined after intravenous injection of $\frac{1}{2}$ g. of glucose per kg. of body weight. In only one was the blood-sugar appreciably higher than fasting level an hour after injection (Case 14) while many of them showed an obvious contrast between the oral and intravenous curves (see Chart). No difference could be made out with this method between cases whose oral glucose curves were markedly different. The 8 curves may be considered normal.

DISCUSSION

Low glucose tolerance curves have been found in sprue and coline disease (Thayson 1926 1929 1932 and Bennett, Hunter and Vaughan 1932). Various explanations have been offered such as deficient absorption or excessive storage of sugar. Recently Himmsworth (1931) made the interesting suggestion that these curves could be compared to the response of subjects previously kept on diets containing large amounts of carbohydrate. patient

not absorbing fat being on virtually high carbohydrate diets. We were therefore careful to keep all our patients on a mixed diet for one week before the actual tests. Besides, in some of our cases the only abnormality was not the absence or the slight extent of any rise in blood sugar but rather its delayed character. This would make us attribute these abnormalities to delayed absorption rather than excessive or too rapid utilisation.

The present paper is only of the nature of a preliminary note and we are not in a position to draw any definite conclusions at the present stage of our work which we intend to pursue further.

SUMMARY

The glucose tolerance of 18 cases of pure ancylostoma infestation has been investigated. In 12 there was some abnormality in the extent of the hyperglycaemic response, its duration or its fall. In 9 of these two or more defects were associated.

The blood sugar curves after intravenous injection of glucose were determined in 8 cases. They were normal and did not correspond to the respective oral responses.

Interference with absorption caused in some way by the presence of the ancylostoma worms and by their bites in the duodenum is surmised as an explanation.

We wish to acknowledge our gratitude to Prof M Omar Bey for his help and advice, and to Prof A Ismail Pacha and Dr M Ibrahim for permission to investigate patients under their care and for their constant encouragement and criticism.

LABOUR COMPLICATED BY THROMBOSIS OF THE MESENTERY

RESECTION OF TEN FEET OF SMALL BOWEL—PATIENT ALIVE AND IN GOOD HEALTH TWENTY-FOUR YEARS LATER

By G GREY TURNER, MS Durb, FRCS Eng
 PROFESSOR OF SURGERY IN THE UNIVERSITY OF LONDON

At a pathological evening at the Medical Society of London held on Jan 11th last, I exhibited a specimen consisting of 10 ft 3 in of the ileum showing the characteristic effects following thrombosis of the mesentery (see Figure). This portion of intestine was excised during the progress of full time labour and the following are the circumstances of the case.

The patient first came under my observation in April, 1910, when I was called into consultation by Dr James Hudson of Newcastle upon Tyne. She was then an unmarried woman, aged 22, who had the misfortune to suffer from a ruptured gastric ulcer following a definite history of stomach illness of 3 years' duration. The operation took place 9 hours after the onset. On exploration

a large perforation was found about the centre of the lesser curve on its anterior aspect. The surrounding area of the stomach wall was much indurated, but the perforation was partly covered by a neighbouring piece of omentum. There was a considerable quantity of dirty looking peritoneal exudate, but this was largely limited to the neighbourhood of the stomach and to the pelvis, the area of the small intestine being free. After closure of the ulcer the peritoneal cavity was thoroughly irrigated, a Keith's glass drainage tube being temporarily inserted into the pelvis through a small suprapubic incision. As a final step, posterior gastro-enterostomy was carried out.

The patient made an uninterrupted recovery and left the private hospital a fortnight after the operation. She continued to make satisfactory progress, and about

The resected portion of small intestine

a year later married and in due course became pregnant. During the early days she was a good deal troubled with sickness, but that soon passed off and in the later stage she enjoyed excellent health.

On a Sunday morning in February of 1913 labour commenced. She was seen by Dr Hudson who in view of the previous history, very carefully examined the abdomen but found everything in perfect order. It was noted that the pulse rate was 72, with a good volume. He left the house with orders that he was to be sent for when necessary. As nothing was heard of the patient during the day, he thought it wise to look in about 9 p.m. and was then surprised to find her looking white and ill with a very quick pulse. He obtained the history that the father had gone up to the bedroom an hour previously and had been rather alarmed because he noticed that when he gave his daughter a good night kiss her face was cold. On examination the uterus was found to be unusually tender and thus, together with the general condition, suggested that there might be some concealed accidental hemorrhage. The pains had ceased. There was no external hemorrhage and the os was only dilated to the size of half a crown. In view of the grave condition Prof Ranken Lyle was called in consultation. After consideration it was concluded that there was probably no accidental hemorrhage but that some intra-abdominal condition was complicating the labour. On further inquiry it was ascertained that the bowels had moved about 5 p.m. and that the motion was normal, but a second evacuation an hour later contained a little blood.

I was asked to see the patient about 1 o'clock the following morning. She then looked exceedingly ill with very blanched lips. The pulse rate was 140, with a very low tension, and there was so much difficulty in breathing that she had to be propped up in bed. The abdomen was distended and tender all over. By this time it looked like a case of severe intra-abdominal hemorrhage, and I could only conclude that the contractions of the uterus had probably torn some very vascular omental adhesions which had resulted from the previous peritoneal inflammation.

tion associated with the ruptured ulcer. The possible significance of the blood in the evacuation was not then appreciated. It was decided to operate at once and arrangements were soon made in the patient's own house.

With Dr Hudson giving the anæsthetic and Prof. Lyle assisting an incision was made from the umbilicus to the pubes. As soon as the peritoneum was opened, blood-stained fluid escaped, and a great mass of deeply congested almost black intestine could be seen in the upper part of the abdominal cavity on the right side. It was impossible to explore the abdomen properly on account of the presence of the uterus and furthermore it was deemed absolutely essential that the latter should be emptied. Cesarean section was therefore performed and a full time perfectly developed but recently dead child was delivered. The incision happened to be through the placenta but there was no excessive bleeding. The uterus was closed with catgut sutures. It was then found that many feet of the lower ileum presented the appearance characteristic of thrombosis of the mesentery. The gut appeared to be absolutely beyond the hope of recovery and therefore resection was carried out the upper part of the small intestine being anastomosed to the cæcum by the lateral method with direct suture. At the conclusion of the operation it was found that the uterus was contracting satisfactorily. A pint of saline was left in the abdomen and the incision was closed with through-and-through silk-worm-gut sutures. During the course of the operation saline was infused under both breasts by the nurse.

The patient stood the operation perfectly well and was really in better condition at the end than at the beginning. The whole proceeding occupied about 1½ hours.

The removed intestine presents the usual conditions found in thrombosis of the mesentery with nothing to give a hint as to ætiology.

During convalescence she ran a temperature as high as 102° F for several days, and at 101° F for about a fortnight. During all this time the pulse was correspondingly quick. At the end of a week from the date of the operation an abscess appeared where saline had been infused beneath the left breast and was opened—it contained gas and was evidently due to *Bacillus coli*. About the third day the lochia were noted to be malodorous; this persisted for a fortnight when a slough was discharged per vaginam after which the lochia gradually became normal. It was thought that probably the uterus had also become infected by the *B. coli* during the operation. It was about three months before the pulse fell to normal but all through convalescence the patient took her food well and eventually made a complete recovery.

For two or three years the bowels were relaxed and usually moved twice daily but there was little inconvenience and she gained weight though she had to be careful with her diet. Within two years she became pregnant again and was delivered of a splendid child 2 years and 8 months after the operation. A year later there was a miscarriage but there have been no further pregnancies and she continues to enjoy excellent health now 24 years since the intestinal resection.

Throughout these years the patient has been so well that she could never be persuaded to submit to any sort of investigation and one can only judge from her general appearance of well being and from the response which she makes to her environment that the economy of the body remains undisturbed.

Just after the conclusion of the case I sent the notes to Dr Hudson who had charge of the patient. His reply is so interesting a commentary on case recording that it is worth quoting—

Dear Mr TURNER,—I have made some additions to your report but no corrections. It is the proper surgical thing to add nothing or subtract nothing from a report making it a bald statement of facts, so when I read your report it was with difficulty I recognised what was an intensely exciting night of it. Why bless my soul, we had a taxi on the run for six hours! Hoping you are well

I remain yours truly

JAMES HUDSON

Abdominal emergencies during pregnancy are rare and in my own experience have been limited to several cases of appendicitis gall-stones and torsion of the pedicle of an ovarian dermoid. During labour they are presumably extremely rare and the example which is here recorded is the only one with which I am familiar.

THE CLINICAL DIAGNOSIS OF POLYARTERITIS NODOSA

WITH A REPORT OF FOUR RECENT CASES

By A W D LEISHMAN B.M. Oxon M.R.C.P. Lond

CHIEF ASSISTANT TO A MEDICAL UNIT ST BARTHOLOMEW'S HOSPITAL, LONDON

Polyarteritis nodosa is a rare disease Oscar Klotz (1917), a pathologist particularly interested in arterial disease states that he performed at least 3000 post-mortem examinations before meeting with a case. In all during the seventy years of its recognised existence about 200 cases have been reported. During the last three years four patients with this disease have been admitted to St Bartholomew's Hospital. In none of these was the diagnosis made during life though in the light of previous experience it was in the last case considered a possibility.

That the problems set by this peculiar disease are intriguing is shown by the number of publications on the subject but in the main it is the pathologist who has claimed it and though all authors agree upon the difficulties and frequent impossibility of clinical diagnosis, surprisingly few have attempted to simplify the clinician's task. It seemed therefore justifiable while giving an account of these recent cases to attempt an analytical clinical survey with a reynthesis which might serve as a foundation for the clinical diagnosis of the condition.

HISTORICAL NOTE

Rokitansky is credited with the first description of the pathological condition given in 1852 but the name of Kussmaul is commonly linked with the disease since he was the first to assign a clinical syndrome to the morbid changes. In 1860 he gave with Mier an account of two cases of a hitherto undescribed peculiar disease of the arteries which is accompanied by Bright's disease and a rapidly progressive general paralysis of the muscles. This he called periarteritis nodosa the name which still persists though Dickson in 1907 suggested the substitution of polyarteritis as being more strictly accurate.

For many years the disease was unrecognised outside Germany and Morley Fletcher is the first English name connected with it. Describing in 1892 what was probably the sixth case he gave an account of a careful study of the microscopic changes and suggested the name arteritis nodo proliferans. The early reports were usually of single cases and concerned mainly with pathology and it was not until 1914 that the first general survey was made by Lamb. He analysed the 35 published cases of polyarteritis nodosa but it is discouraging to the clinician to note his conclusion that saving the presence of typical skin nodules diagnosis during life is impossible.

In 1921 P. Meyer briefly discussed the points of diagnostic value obtained from a review of 20 cases but the monumental work of Grüber in 1926 was

not absorbing fat being on virtually high carbohydrate diets. We were therefore careful to keep all our patients on a mixed diet for one week before the actual tests. Besides, in some of our cases the only abnormality was not the absence or the slight extent of any rise in blood sugar but rather its delayed character. This would make us attribute these abnormalities to delayed absorption rather than excessive or too rapid utilisation.

The present paper is only of the nature of a preliminary note and we are not in a position to draw any definite conclusions at the present stage of our work which we intend to pursue further.

SUMMARY

The glucose tolerance of 18 cases of pure ancylostoma infestation has been investigated. In 12 there was some abnormality in the extent of the hyperglycaemic response, its duration or its fall. In 9 of these two or more defects were associated.

The blood sugar curves after intravenous injection of glucose were determined in 8 cases. They were normal and did not correspond to the respective oral responses.

Interference with absorption caused in some way by the presence of the ancylostoma worms and by their bites in the duodenum is surmised as an explanation.

We wish to acknowledge our gratitude to Prof M Omar Bey for his help and advice, and to Prof A Ismail Pacha and Dr M Ibrahim for permission to investigate patients under their care and for their constant encouragement and criticism.

LABOUR COMPLICATED BY THROMBOSIS OF THE MESENTERY

RESECTION OF TEN FEET OF SMALL BOWEL—PATIENT ALIVE AND IN GOOD HEALTH TWENTY FOUR YEARS LATER

By G GRAY TURNER, M.S. Durh., F.R.C.S. Eng.
 PROFESSOR OF SURGERY IN THE UNIVERSITY OF LONDON

At a pathological evening at the Medical Society of London held on Jan 11th last, I exhibited a specimen consisting of 10 ft 3 in. of the ileum showing the characteristic effects following thrombosis of the mesentery (see Figure). This portion of intestine was excised during the progress of full time labour and the following are the circumstances of the case.

The patient first came under my observation in April, 1910, when I was called into consultation by Dr James Hudson of Newcastle-upon-Tyne. She was then an unmarried woman, aged 22 who had the misfortune to suffer from a ruptured gastric ulcer following a definite history of stomach illness of 3 years' duration. The operation took place 9 hours after the onset. On explora-

tion a large perforation was found about the centre of the lesser curve on its anterior aspect. The surrounding area of the stomach wall was much indurated, but the perforation was partly covered by a neighbouring piece of omentum. There was a considerable quantity of dirty looking peritoneal exudate, but this was largely limited to the neighbourhood of the stomach and to the pelvis, the area of the small intestine being free. After closure of the ulcer the peritoneal cavity was thoroughly irrigated, a Keith's glass drainage tube being temporarily inserted into the pelvis through a small suprapubic incision. As a final step, posterior gastro-enterostomy was carried out.

The patient made an uninterrupted recovery and left the private hospital a fortnight after the operation. She continued to make satisfactory progress, and about

The resected portion of small intestine

a year later married and in due course became pregnant. During the early days she was a good deal troubled with sickness, but that soon passed off and in the later stages she enjoyed excellent health.

On a Sunday morning in February of 1913 labour commenced. She was seen by Dr Hudson who in view of the previous history, very carefully examined the abdomen but found everything in perfect order. It was noted that the pulse rate was 72, with a good volume. He left the house with orders that he was to be sent for when necessary. As nothing was heard of the patient during the day, he thought it wise to look in about 9 p.m. and was then surprised to find her looking white and ill with a very quick pulse. He obtained the history that the father had gone up to the bedroom an hour previously and had been rather alarmed because he noticed that when he gave his daughter a good night kiss her face was cold. On examination the uterus was found to be unusually tender and this, together with the general condition, suggested that there might be some concealed accidental hemorrhage. The pains had ceased. There was no external hemorrhage and the os was only dilated to the size of half a crown. In view of the grave condition Prof Ranken Lyle was called in consultation. After consideration it was concluded that there was probably no accidental hemorrhage but that some intra-abdominal condition was complicating the labour. On further inquiry it was ascertained that the bowels had moved about 5 p.m., and that the motion was normal but a second evacuation an hour later contained a little blood.

I was asked to see the patient about 1 o'clock the following morning. She then looked exceedingly ill with very blanched lips. The pulse rate was 140, with a very low tension, and there was so much difficulty in breathing that she had to be propped up in bed. The abdomen was distended and tender all over. By this time it looked like a case of severe intra-abdominal hemorrhage, and I could only conclude that the contractions of the uterus had probably torn some very vascular omental adhesion which had resulted from the previous peritoneal inflamma-

tion associated with the ruptured ulcer. The possible significance of the blood in the evacuation was not then appreciated. It was decided to operate at once and arrangements were soon made in the patient's own house.

With Dr Hudson giving the anæsthetic and Prof Lyle assisting an incision was made from the umbilicus to the pubes. As soon as the peritoneum was opened blood stained fluid escaped and a great mass of deeply congested, almost black intestine could be seen in the upper part of the abdominal cavity on the right side. It was impossible to explore the abdomen properly on account of the presence of the uterus and furthermore it was deemed absolutely essential that the latter should be emptied. Caesarean section was therefore performed and a full-time perfectly developed but recently dead child was delivered. The incision happened to be through the placenta, but there was no excessive bleeding. The uterus was closed with catgut sutures. It was then found that many feet of the lower lumen presented the appearance characteristic of thrombosis of the mesentery. The gut appeared to be absolutely beyond the hope of recovery and therefore resection was carried out the upper part of the small intestine being anastomosed to the cæcum by the lateral method with direct suture. At the conclusion of the operation it was found that the uterus was contracting satisfactorily. A pint of saline was left in the abdomen and the incision was closed with through-and-through silk-worm gut sutures. During the course of the operation saline was infused under both breasts by the nurse.

The patient stood the operation perfectly well and was really in better condition at the end than at the beginning. The whole proceeding occupied about 1½ hours.

The removed intestine presents the usual conditions found in thrombosis of the mesentery with nothing to give a hint as to ætiology.

During convalescence she ran a temperature as high as 102° F for several days, and at 101° F for about a fortnight. During all this time the pulse was correspondingly quick. At the end of a week from the date of the operation an abscess appeared where saline had been infused beneath the left breast and was opened—it contained gas and was evidently due to *Bacillus coli*. About the third day the lochia were noted to be malodorous; this persisted for a fortnight when a slough was discharged per vaginam after which the lochia gradually became normal. It was thought that probably the uterus had also become infected by the *B. coli* during the operation. It was about three months before the pulse fell to normal, but all through convalescence the patient took her food well and eventually made a complete recovery.

For two or three years the bowels were relaxed and usually moved twice daily but there was little inconvenience and she gained weight though she had to be careful with her diet. Within two years she became pregnant again and was delivered of a splendid child 2 years and 8 months after the operation. A year later there was a miscarriage but there have been no further pregnancies and she continues to enjoy excellent health now 24 years since the intestinal resection.

Throughout these years the patient has been so well that she could never be persuaded to submit to any sort of investigation and one can only judge from her general appearance of well being and from the response which she makes to her environment that the economy of the body remains undisturbed.

Just after the conclusion of the case I sent the notes to Dr Hudson who had charge of the patient. His reply is so interesting a commentary on case recording that it is worth quoting—

Dear Mr TURNER—I have made some additions to your report but no corrections. It is the proper surgical thing to add nothing or subtract nothing from a report making it a bald statement of facts, so when I read your report it was with difficulty I recognised what was an intensely exciting night of it. Why bless my soul we had a taxi on the run for six hours! Hoping you are well.

I remain yours truly,

JAMES HUDSON

Abdominal emergencies during pregnancy are rare and in my own experience have been limited to several cases of appendicitis, gall-stones and torsion of the pedicle of an ovarian dermoid. During labour they are presumably extremely rare and the example which is here recorded is the only one with which I am familiar.

THE CLINICAL DIAGNOSIS OF POLYARTERITIS NODOSA

WITH A REPORT OF FOUR RECENT CASES

By A W D LEISHMAN B.M. Oxon M.R.C.P. Lond

CHIEF ASSISTANT TO A MEDICAL UNIT, ST BARTHOLOMEW'S HOSPITAL, LONDON

Polyarteritis nodosa is a rare disease. Oscar Klotz (1917) a pathologist particularly interested in arterial disease states that he performed at least 3000 post-mortem examinations before meeting with a case. In all, during the seventy years of its recognised existence about 200 cases have been reported. During the last three years four patients with this disease have been admitted to St Bartholomew's Hospital. In none of these was the diagnosis made during life though in the light of previous experience it was in the last case considered a possibility.

That the problems set by this peculiar disease are intriguing is shown by the number of publications on the subject but in the main it is the pathologist who has claimed it and though all authors agree upon the difficulties and frequent impossibility of clinical diagnosis, surprisingly few have attempted to simplify the clinician's task. It seemed therefore justifiable while giving an account of these recent cases to attempt an analytical clinical survey with a resynthesis which might serve as a foundation for the clinical diagnosis of the condition.

HISTORICAL NOTE

Rokitansky is credited with the first description of the pathological condition given in 1852 but the name of Kussmaul is commonly linked with the disease since he was the first to assign a clinical syndrome to the morbid changes. In 1866 he gave with Maier an account of two cases of a hitherto undescribed peculiar disease of the arteries which is accompanied by Bright's disease and a rapidly progressive general paralysis of the muscles. This he called *periarteritis nodosa* the name which still persists, though Dickson in 1907 suggested the substitution of *polyarteritis* as being more strictly accurate.

For many years the disease was unrecognized outside Germany and Morley Fletcher is the first English name connected with it. Describing in 1892 what was probably the sixth case he gave an account of a careful study of the microscopic changes and suggested the name *arteritis nodosa proliferans*. The early reports were usually of single cases and concerned mainly with pathology and it was not until 1914 that the first general survey was made by Lamb. He analysed the 38 published cases of *polyarteritis nodosa* but it is discouraging to the clinician to note his conclusion that saving the presence of typical skin nodules diagnosis during life is impossible.

In 1921 P. Meyer briefly discussed the points of diagnostic value obtained from a review of 20 cases but the monumental work of Gräber in 1926 was

based on 113 cases, though from inadequate description many of these are of little value

Since then, from the clinical point of view, reviews by Strong (1928) and Curtiss and Coffey (1929) are outstanding. Between them these authors collected and analysed a further 38 cases published in English, while a French paper by Cathala (1929) is noteworthy as being one of the few direct attacks upon the problems of clinical diagnosis.

PATHOLOGY

Though the pathology of the disease is outside the scope of this article, in brief it may be said that polyarteritis nodosa affects the small and medium sized arteries—in order of frequency those of the kidneys, heart, liver, the alimentary tract, mesentery, skeletal muscles, pancreas, peripheral nerves, and the brain.

Microscopically, whitish grey coloured nodules of varying size are seen upon the affected artery. Not infrequently aneurysms are formed and may rupture. The vessels tend to thrombose and the organ supplied is consequently often the site of numerous infarcts.

Microscopically it seems, although it is not universally accepted, that the earliest change is in the adventitia where great aggregation of polymorphonuclear cells together with eosinophils and monocytes is seen. The media undergo necrosis, the internal elastica lamina ruptures, and there is much proliferation of the intima. Thrombosis occurs but in healed lesions the thrombus may be recanalised. Other changes in the body are entirely secondary to the arterial disease.

ÆTIOLOGY

The cause of the disease is still unknown. For many years syphilis was suspected but with the advent of the Wassermann reaction this has had to be abandoned. The clinical course suggests an infection but all attempts to recover a specific organism both during life and at autopsy have failed. Harris and Friedrichs (1922) claimed to have transmitted the disease to rabbits by inoculation of post mortem material, but this has never been repeated. It is interesting that an apparently identical morbid condition has been found in certain of the lower animals such as the dog, the pig, the calf, and the deer.

Infection by an ultramicroscopic filtrable virus is a possibility, but Ophüls (1923), drawing attention to similarities between polyarteritis nodosa and acute rheumatism, put forward a further hypothesis that this disease represents another manifestation of a streptococcal allergic state.

The Clinical Picture

In the account which follows the diagnostic standpoint has been maintained throughout, it includes therefore only those points which are of sufficiently frequent recurrence to be of value in diagnosis. Based upon the six most important clinical surveys it represents the study of at least 150 cases.

The disease occurs three to four times more often in males. It most commonly affects those aged 40–49, the extremes recorded being 3 months and 78 years.

SYMPTOMS AND SIGNS

The previous history and family history are of no significance. The onset is acute or gradual in almost equal numbers. The initial symptoms are not especially enlightening save that it is worth recording

in order of frequency complaints of (1) muscular pains, (2) fever, (3) abdominal pains, (4) œdema, and (5) general weakness.

The fifteen fundamental signs of diagnostic value in their order of frequency of occurrence are as follows—

- 1 *Fever* which does not commonly exceed 100° – 101° F and is usually of the remittent type, but afebrile intervals with exacerbations of pyrexia are not uncommon.
- 2 *Increasing general weakness* with loss of weight.
- 3 *Albuminuria*.
- 4 *Cylindruria* of hyaline and granular type commonly with microscopic hematuria.
- 5 *Leucocytosis* to an average figure of 15,000 to 20,000 per cubic millimetre with absolute increase in the polymorphonuclear cells and occasional eosinophilia.
- 6 *Anæmia* of a microcytic type and only moderately severe.
- 7 *Tachycardia* out of proportion to the fever.
- 8 *Abdominal symptoms* and alimentary disturbance. Most commonly these are cramp like or colicky pains, or sensations of soreness and heaviness across the abdomen. Often the abdomen has been surgically explored. Anorexia is frequent, with bowel disorder, both constipation and diarrhoea. Vomiting is less common and hematemesis, melæna and acute perforation of the gut are occasional emergencies.
- 9 *Polyneuropathy* of peripheral type which affects any or all four limbs with considerable motor loss and muscular wasting, but slighter sensory changes.
- 10 *Polymyositis* is especially pronounced in the limb muscles and shows itself by agonising cramps and tender wasting muscles.
- 11 *œdema* is of cardiac distribution.
- 12 *Cutaneous lesions*. The most characteristic lesion is a nodule varying in size from a millet seed to a pea, fixed in the skin but moving on the deeper tissues, occasionally these are purpuric or vesicular. They are painless and frequently evanescent, all trace of a nodule may have disappeared within 24 hours. More rarely and especially in acute forms of the disease a generalised skin eruption is seen. This may be of the hæmorrhagic type, petechial, purpuric or ecchymotic, and occasionally a simple erythema or urticaria.
- 13 *Cardiac signs* are those of heart failure without obvious cause, though electrocardiographic changes may suggest coronary disease—e.g. thrombosis.
- 14 *Enlargement of the liver* (but not of the spleen) with tenderness.
- 15 *Respiratory symptoms*—Cough with diffuse signs of bronchitis and bronchiolitis.

It might be hoped that characteristic changes would be observed in the retinal arteries. Unfortunately this is not the case. The only changes seen are occasionally those of albuminuric retinitis although in one case at least (1935) occlusion of the central retinal artery occurred.

Even in tabulated form the manifestations of this disease appear distressingly protean. Various authors attempting to simplify this picture have distinguished different clinical types of the disease, thus von Schrötter (1899) recognised five groups (1) renal, (2) abdominal, (3) neuromuscular, (4) cardiac and (5) bronchial. In practice, however, such division fails, for the very reason that complexity of symptom is one of the most characteristic features of the disease.

The basic clinical picture is that of a *severe progressive toxæmia characterised by fever, muscular asthenia, loss of weight and anæmia*. These are the symptoms of the active disease process itself, all other signs can be ascribed to local arterial lesions, although frequently these latter effects are so impressive that the general character of the disease may be obscured. This is well seen in Case 3 reported here. If this point is realised, the occasional appearance of more dramatic symptoms, like those of cerebral or meningeal disease, can be brought into

line with the rest of the picture and will not confuse the issue

COURSE

The disease seems almost invariably fatal, although four undoubted cases have recovered and it seems likely that an occasional case may recover unrecognized. The average duration of the illness is from three to four months and the commonest terminations are (1) cardiorenal failure (2) marasmus and far less commonly (3) sudden local vascular accidents.

Chronic forms have been occasionally met with. A very remarkable case with a total duration of 12 years illness was described by Macalaine and Nicoud (1932) and one of four years course by Arkin (1930). Each of these was characterised by alternating periods of remission and exacerbation and this Arkin suggests is a feature of the less acute types since each febrile recrudescence indicates the development of fresh arterial lesions.

No treatment has been found of any value.

DIAGNOSIS

The difficulties are obvious and are reflected in the variety of diagnoses that have been made. Hidden sepsis, typhoid fever, acute abdominal condition, trichiniasis, nephritis, peripheral neuritis, myositis, miliary tuberculosis, dysentery, purpura, septic endocarditis, meningitis and encephalitis have at various times been simulated. At least 30 cases however have been diagnosed during life and though some of these were only discovered at exploratory laparotomy and others after biopsy of cutaneous lesions in a small group the diagnosis has been made on clinical grounds alone.

The rarity of correct diagnosis must at least in part be due to unfamiliarity with the disease. It is suggested therefore that if the following points are borne in mind this difficulty may to some extent be overcome. (1) The possibility of polyarteritis nodosa should be considered—

- (a) In any illness characterised by severe progressive toxæmia with fever, muscular anæmia and loss of weight.
 - (b) In any illness having the character of an infection where there is complete failure to locate the infection.
 - (c) In any illness where there are unusual and apparently unrelated combinations of signs for example nephritis associated with peripheral neuritis, heart failure, skin rashes or abdominal symptoms.
- (2) The diagnosis of polyarteritis nodosa being under consideration reference should be made to the fifteen cardinal symptoms and signs previously given.
- (3) The diagnosis may often be clinched by biopsy of cutaneous lesions or in their absence of skeletal muscle.

Case histories *

CASE 1

Mrs A. B. aged 60 a retired hospital cook was admitted to hospital on May 8th 1933 under the care of Dr Geoffrey Evans, complaining of general weakness, cough and fever.

History.—Five months previously she began to feel off colour with loss of energy and strength. One month before admission she lost her voice for a few days and had shivering attacks at night. There was an evening rise in temperature to about 100° F. and she remained in bed. Two weeks later she started to cough with much colourless watery sputum and the temperature remained continuously raised. She noticed increasing

shortness of breath with palpitations and on occasions some swelling of the ankles. There had been no true night sweats but she had lost weight. At the age of 57 she had had pneumonia, and when 53 she had a right sided stroke from which she made a gradual complete recovery.

The family history was not significant except that her mother had died of chronic phthisis. Habits were satisfactory.

On examination she was pale and wasted and looked older than her years, slightly dyspnoic and cyanosed. The temperature was 101° F. pulse rate 110 and respirations 20. The eyes were normal with clear fundi and retine and normal pupil reactions. Fauces were somewhat inflamed; she was edentulous. A lymph node was palpable in each anterior triangle of the neck and in the right axilla. The chest showed pigeon breast deformity and was very poorly covered. Movement was poor but equal percussion note resonant generalised rhonchi were heard with fine crepitations at both bases especially in the left axilla. The heart was normal in size and the sounds regular and natural but the rate was rapid (100-120). The radial artery was thickened the blood pressure 140/70. The abdomen showed no abnormality except that the liver was palpable a finger breadth below the costal margin. There was some stiffness of most joints and many showed the appearances of chronic rheumatoid arthritis. The tendon reflexes in the upper limbs were normal. The abdominal reflexes were not obtained. Knee-jerks were present. Ankle jerks absent. Plantar response flexor. Sensation was not tested. The urine output was normal, specific gravity 1010-1020, no abnormal constituent found; on culture it was sterile. Blood count—

Red cells	5,240,000	White cells	35,000-40,000
Hæmoglobin	74%	Polymorphs	27,300
Colour Index	0.7	Lymphocytes	7,900
		Eosinophils	720

Widal reaction negative to enteric group *Brucella abortus* and *B. melitensis*. Blood culture was sterile. Repeated examination of sputum revealed no tubercle bacilli. Radiograms of chest showed no abnormality in the lung fields.

Course.—The fever continued the temperature swinging in 24 hours between 99 and 102° F. and the pulse between 110 and 120 per minute. The general condition showed little change. The signs in the lungs persisted and gave rise to a tentative diagnosis of miliary tuberculosis despite negative sputa and radiograms. On June 20th (6 weeks after admission) she first complained of abdominal discomfort and this became considerable though on repeated examination no definite abnormality could be detected. The stools were now loose but contained no blood. On July 2nd (8 weeks after admission) she complained of pain on micturition and a specimen of urine was found to contain red and white blood-cells, a few granular casts, and *Bacillus coli* in profusion. The infection cleared with treatment but the urine continued to contain albumin and macroscopic blood. Weight had been lost rapidly—over a stone in two months since admission—and she became progressively weaker. Examination of the abdomen now revealed general tenderness especially in both posterior renal angles but neither kidney could be felt. By July 18th (10 weeks after admission) she was mentally wandering incontinent of urine and gradually became drowsy. The blood urea was found to be 120 mg. per 100 c.c. The temperature became subnormal and she slowly sank into a quiet coma and died on July 22nd 10½ weeks after admission.

Autopsy.—Typical nodules were seen in the mesentery. On section the kidneys showed appearances suggestive of focal abscess formation, and on microscopic examination all the kidney vessels showed extreme leprosy of inflammatory change with numerous zones of infarction. The coronary arteries showed similar changes and to a less extent those of the liver.

CASE 2

Mr C. D. aged 45, tape measure maker was admitted to hospital on Jan 2nd 1934 under the care of Prof. F. H. Fraser complaining of pains and numbness in the legs and loss of use of the legs.

* A full account of the pathology of these cases will be published by Dr. Robt. Smith.

History—He was well until 6 weeks before admission when he noticed, on walking, cramp like pains in the calf muscles, these were at first relieved by resting. He next found difficulty in straightening the legs and the pains became worse. He managed, however, to remain at work until 4 weeks before admission when he had to rest with the feet up. At this time he lost his appetite and he thought he was rapidly losing flesh. The bowels were constipated. While in bed 13 days before admission, he suddenly felt pins and needles in the left foot and on putting the foot to the ground he was unable to feel the floor though he could still walk. Two days later the right foot became similarly affected and soon he was unable to use his legs as they "gave" under him. The cramp like pains ceased but he was completely paralysed and the feet now became increasingly swollen. There was 4 days before admission a gradual onset of numbness in the left hand with loss of power in the whole limb. Apart from these symptoms he had had a tendency to vomit after breakfast and this had become worse during the last two weeks. The past history was not significant save that his work brought him in contact with lead paint. He was a temperate man.

On examination he was thin, pale and slightly breathless. The temperature was 101.2° F, the pulse rate 100, and respirations 29. The eyes were normal, fundi and retinae clear. Teeth were fair, tongue furred, tonsils and fauces healthy. The thyroid was normal in size and there were no enlarged lymph nodes in the neck, axilla, or groins. The chest appeared normal but percussion note was impaired at both bases and many crepitations were heard. The heart was slightly enlarged, the apex beat being $\frac{1}{2}$ in outside the nipple in the fifth space. At the apex a soft systolic bruit followed the first sound and was conducted into the axilla, the sounds otherwise were normal and the rhythm was regular. The radial artery appeared healthy and the blood pressure was 146/82 mm Hg. The abdomen was protuberant and tympanic there were no signs of free fluid. No viscus was palpable and there was no tenderness. The abdominal reflexes were present. There was oedema of the lower third of the legs and of the feet on both sides.

Nervous system—Cranial nerves were normal. The arms showed no obvious wasting, but there was much loss of power in all movements of the left arm and hand and diminished sensation to cotton wool in the ulnar and radial nerve distribution of the left hand. Tendon reflexes were symmetrical but obtained with difficulty. In the legs the thigh and calf muscles were flaccid and there was much wasting below the knees. Only slight movement at the left hip joint was possible, all other movements of both legs were abolished and there was bilateral foot-drop. There was loss of light touch and pin prick sensation over a stocking area in both legs, the left being more complete than the right. The right knee jerk was obtained but the left knee jerk and both ankle jerks were absent, the plantar responses were flexor. The urine output was satisfactory, specific gravity 1020, it contained a trace of albumin but no other abnormal constituent. The blood—

Red cells	5 150 000	White cells	19 000
Hæmoglobin	80 %	Polymorphs	15 580
Colour index	0.8	Lymphocytes	2 660
		Large mononuclears	570
		Eosinophils	100

The Wassermann and Sigma reactions were negative. Cerebro spinal fluid entirely normal. Wassermann and Sigma reactions negative. The sputum was three times negative for tubercle bacilli.

Diagnosis—Toxic polyneuritis

Course—After a week the temperature had gradually fallen to 99° F but the pulse and respirations remained at the previous level. He complained much of paræsthesia and muscle cramps in both legs and some tingling in the right hand was felt but power in this limb remained good. He continued to cough much watery sputum and the lung signs were increased. The urine now contained a cloud of albumin and the deposit showed granular casts. The blood urea was 160 mg per 100 c cm. A week later after some temporary slight improvement, he relapsed became dyspnoic and exanosed and coughed up blood stained sputum. The temperature, blood, and

respirations all rose, there were signs of consolidation at the base of the left lung. The next day, though seeming brighter he collapsed while being washed and died suddenly, two weeks after admission.

Autopsy—The vascular lesions were widespread. The heart was dilated but the coronary arteries appeared healthy. There was an effusion in the left pleural cavity and broncho-pneumonic changes in the left lung. The intestines were distended and numerous nodules involved the whole of the alimentary tract and the omentum. The liver was congested and there was much arteritis with aneurysm formation. The kidneys had several infarcts and the arteries in these showed acute changes of polyarteritis. The arteries to the leg muscles and nerves were considerably affected and the sciatic nerve itself was oedematous and reddened.

CASE 3

Mrs E. F., aged 58, housewife, was admitted to hospital on Jan 9th, 1934, under the care of Dr Hinds Howell, complaining of passing little urine, vomiting, and abdominal pain after micturition.

History—She had been well until five weeks before, when she had an illness characterised by malaise, head ache, and upper respiratory catarrh with cough. This was diagnosed as influenza. A week later she began to have abdominal discomfort after passing water and she noticed she passed very little urine and that it was highly coloured. She felt very poorly, having constant frontal headache and vomiting after every meal. The urine was examined by her doctor and found to contain much albumin. There had been no visual disturbances. She had been subject to recurrent cough with sputum but there was no history of previous kidney disease, tonsillitis, or scarlet fever.

On examination she was pale and ill, perpetually retching or coughing. The skin was coarse and dry. Temperature 100.6° F, pulse rate 92, and respirations 20. The eyes were normal as regards pupil reactions, discs, and retinae. The tongue was furred and dry, fauces inflamed, and there was gross dental sepsis. The thyroid was normal in size. The chest appeared normal but many coarse râles were heard, especially at the left base. The heart was not enlarged, the first sound at the apex was soft but otherwise the sounds were clear and regular. The blood pressure was 125/75 mm Hg. The abdomen was normal, no viscus being palpable. Neither the knee jerks nor the ankle jerks were obtained, the plantar responses were flexor. There was no oedema of the ankles. The urine was highly coloured and reduced in quantity, the specific gravity was 1018, there was a cloud of albumin present, but no other abnormal constituent. The deposit contained granular casts and a number of red blood corpuscles. Culture was sterile. Blood count—

Red cells	4 820 000	Colour index	0.80
Hæmoglobin	84 %	White cells	10,800
Blood urea	85 mg/100 c cm		

Diagnosis—Chronic nephritis, bronchial catarrh, and uræmia.

Course—After one week the temperature and pulse fell and remained normal and the patient felt rather better though there was still some nausea and retching. The signs in the chest persisted. The urine output was greatly diminished and abdominal discomfort was much complained of, especially after micturition. On Jan 22nd some teeth were extracted under gas and oxygen anaesthesia and again on Jan 26th. Following the second extraction there was considerable hæmorrhage from the gums and her general condition deteriorated with increase in the vomiting, exanosis, and gradual decline into coma. The temperature fell, the chest became full of moist sounds, and she died on Jan 27th, 18 days after admission. The blood urea on the day before her death was 380 mg per 100 c cm.

Autopsy—No typical appearances were seen macroscopically. The kidney cortex was reduced and the surface had a peculiar blotchy appearance. On microscopic section however the larger vessels of the kidney showed pronounced acute periarteritic changes, but there was no infarction. The arteries in the liver were similarly affected though to a lesser degree.

CASE 4

Miss G H, aged 47 lady's companion was admitted to hospital on June 30th 1936, under the care of Dr Geoffrey Evans complaining of general weakness.

History.—For 2½ years she had suffered from nasal catarrh with frequent sneezing and also much cough with a little phlegm. She had become rather breathless and easily tired and had lost 4 st in weight within the last two years. One month before admission she had three teeth extracted under local anæsthesia (cocaine) and the following day her feet became swollen. A few days later after taking a medicine containing 5 grains of potassium iodide the whole of the face became swollen and the eyes closed. After treatment with starch poultices the skin desquamated leaving a painful weeping surface but this had since gradually healed. At this time she was very weak and breathless and the ankles remained swollen, so the major part of the day was spent in bed. Two days before admission on putting her feet to the ground she found they would no longer support her. The appetite had been fairly good and she had taken a full and varied diet. The digestion was good and the bowels work d normally. There were no other symptoms of note. Her habits were excellent and the only other medicine taken before admission was Easton's syrup. She had had no previous illnesses. No family history of allergy was obtained.

On examination she was a thin tired looking woman, breathless and speaking slowly with an effort but mentally alert. The temperature was 99 F, pulse rate 140 and respirations 20. The musculature was generally flabby and she was unable to turn over in bed by herself. The face was covered by a healing granulating surface, the skin elsewhere was dry and inelastic. On the dorsum of the hands and the sides of the trunk a peculiar eruption was seen. This consisted of mauve-coloured raised patches up to the size of a shilling several of which showed surface scaling; they were faintly reminiscent of lichen planus. The eyebrows were deficient but the hair on the head was normal. Mucous membranes were pale. Lujal reactions were normal and fundi and retinas were clear. The tongue was furred, fauces and tonsils were normal but there was considerable dental sepsis. The thyroid was normal and there were no enlarged glands in the neck, axillæ or groins. The veins in the neck were full and pulsating. The chest was poorly covered but movement was good. Breath sounds were harsh with prolonged expiration universally; rhonchi and sibilus were heard in the upper zones of both lungs and coarse râles at the bases. The cardiac impulse forcible and heaving was seen in the sixth space the apex beat being in the nipple line. The heart was not enlarged to the right of the sternum. The rhythm was regular, a loud systolic bruit replaced the first sound at the apex, but the sounds at the base were clear though the pulmonary second sound was much accentuated. The radial artery was somewhat thickened. The blood pressure was 130/110. The abdomen was very lax and abdominal reflexes were not obtained. The liver enlarged and palpable three fingers breadth below the costal margin was smooth on surface and tender. No other viscera was palpable; there was no tenderness and no free fluid. The arms appeared very thin with muscles much wasted, there was bilateral wrist drop. Movements of the upper arms were weak, the grip was poor and no voluntary movement was possible at the wrist joints. All tendon reflexes in the upper limbs were present symmetrically; there was no sensory loss but the muscles were tender on pressure. All the muscles of both legs were wasted and both feet were redematous. The legs lay externally rotated and there was bilateral foot and toe-drop. Both little toes were blue and cold but pulsation was felt in the dorsalis pedis arteries. Movements at the hip and knee were weak and required great effort and there was no movement at either ankle joints. Both knee jerks were absent; the right ankle-jerk was also absent but the left ankle jerk was obtained on reinforcement. Plantar responses were flexor. There was some hypoaesthesia over the dorsum of both feet and vibration sense was markedly diminished.

The urine was diminished in output; specific gravity 10.5; it contained albumin (0.14 g per 100 ccm)

centrifuged deposit showed 8-10 white cells and 2-4 red cells per field and many granular and epithelial casts on culture it was sterile. Blood count—

Red cells	3 750,000	Blood urea	
Hæmoglobin	70 %		
Colour index	0.9	Cholesterol	37 mg/100 ccm
White cells	11,000		
Polymorphs	0.433	Serum proteins	130 mg/100 ccm
Lymphocytes	1.400		
Eosinophils	55	Albumin	3.1 g/100 ccm
Large mononuclears	165	Globulin	1.9

Radiography of the chest showed general enlargement of the heart and appearances compatible with congestion in the lung fields. Electrocardiogram showed a regular sinus rhythm at 107 per minute with low voltage QRS complex and inverted T wave in lead III.

A diagnosis was not made but for the most part opinion favoured a conception of a cardiovascular renal atherosclerosis with heart failure and a peripheral polyneuritis of unknown toxic origin.

Course.—The temperature remained about 99 F and the pulse-rate averaged 110. The oedema increased in the legs and in the lumbar region the right hand also became swollen. The blood pressure improved to 168/98 mm Hg following digitalis therapy but the patient became progressively weaker and in the second week lost control of the sphincters. A fresh violet-coloured eruption made its appearance on the left hand. Dr A C Roxburgh was unable to identify this with any known skin disease. At the end of the second week temperature, pulse- and respiration rates began to rise and a crop of petechiæ appeared on the trunk and limbs. A blood culture taken at this time remained sterile. The blood urea increased to 90 mg per 100 ccm, and the patient slowly sank into a coma with low-grade delirium and died on July 18th two and a half weeks after admission.

Autopsy.—There were widespread changes. The heart was dilated and there was a recent infarct at the apex with much softening of the muscle. Bilateral pleural effusions were present and the lungs showed many small infarcts. Small nodules were seen on the arteries of the mesentery. Both kidneys and the liver contained infarcts and microscopically the arteries of every organ examined showed the changes of polyarteritis. The sciatic nerves were swollen with patchy haemorrhagic areas; many vessels in their neighbourhood contained nodosities.

COMMENTS

Reviewing these cases in the light of the previous discussion it is interesting to note that three out of the four were women and that they were all beyond the common age period. In Cases 1, 3 and

4 the earliest complaints were typical—i.e., general weakness, fever, and pains in the legs. The course of the illness was acute (8 weeks) in two cases, slowly but gradually progressive in one (7½ months), and of long duration (2 years) with an acute terminal exacerbation in the last. In the Table are summarised the fifteen cardinal signs of diagnostic value in relation to each case.

From this it will be seen that Case 4 presented a typical clinical picture and should certainly have been diagnosed. Cases 1 and 2 were reasonably suggestive, while Case 3 with such purely localised signs was obviously beyond the possibility of clinical diagnosis.

Summary

Four new cases of polyarteritis nodosa are described in detail. The clinical findings are reviewed and from a survey made of 150 cases previously published a composite clinical picture has been drawn. It is believed that familiarity with this clinical picture will facilitate the diagnosis of the disease, which until now has generally been first recognised post mortem.

I am indebted to the physicians in charge for permission to publish the notes of these cases, and wish to express my thanks to Dr A. H. T. Robb Smith for the post mortem reports and to Dr Geoffrey Evans for much helpful criticism.

CYSTIC DEGENERATION OF THE CHORIONIC VILLI IN THE SIXTH DECADE

By CHARLES HOLLÓSI, M.D.

(From the Surgical Clinic, University of Tisza István Debrecen, Hungary)

To the pathologist the aetiology of cystic degeneration of the chorion villi is still unsettled. The fact that none has been accepted explains the numerous and extraordinary theories that have been advanced to account for its occurrence.

Some claim it to be foetal, others maternal in origin, while some even attribute it to a certain type of sperm cell. The following are other factors held to be responsible—

Degeneration of the ovum or its parts caused by the hyperfunction of the corpus luteum. Hypofunction of the corpus—a circulatory disorder, injury to the placental capillaries by toxic products from the maternal blood stream—over production of mucous tissue within the villi into which it extends at first alone but afterwards accompanied by blood vessels—a maldevelopment of the blood vessels.

Among the more notable experiments are those of Aichel (Sathmary 1926) who by macerating the

placenta in animals was able to bring about cystic degeneration in the chorion villi. In hydatidiform mole secondary corpus luteum cysts appear in the ovary, these vary in size and are generally bilateral. Cottalorda (1923) has shown that cystic degeneration in the ovary was present in 50 per cent. of the cases of cystic degeneration of the chorion villi, and in 94 per cent of the cases of chorion epithelioma.

The appearance of a vesicular mole is peculiar. The mass may be as large as a man's head, covered more or less with decidua, which upon incision reveals innumerable small cysts, some as large as grapes or even as hen's eggs, connected with each other or with the base of the chorion by pedicles of varying thickness. A microscopical section through a villus shows distended cells, with an over production of epithelial cells, the Langhans' cell layer, and the irregular syncytium cells.

Cystic degeneration of the chorion villi may occur at any age. Evidently the disease occurs most frequently in multiparae between forty and fifty and very seldom above this age, one case is reported of a girl aged nine. Estimates of its incidence vary from 1/650 to 1/1347.

CASE HISTORY

A multipara, aged 54, was sent by her physician with a diagnosis of malignant tumour of the uterus. Menstruation had begun at 13, recurring at regular 28 day periods lasting 4–5 days. She married at the age of 16, and had 15 normal pregnancies. At the age of 44, in her last pregnancy, she gave birth to twins, after which her periods stopped. In January, 1924, there was a slight haemorrhage and its repetition led her to visit her physician, who upon examination diagnosed malignant tumour of the uterus and directed her to the clinic for operation.

The day after her arrival at the clinic a rather serious haemorrhage occurred necessitating physiological infusions. A rather large mass of cystic chorion villi was discharged (Fig. 1). To check the haemorrhages after the uterine cavity had been well irrigated drugs were given to contract the uterus.

The patient was medium sized and well developed. Thoracic organs normal.

Vaginal examination—Scars of perineal laceration due to delivery. Large vaginal vault erosion of external os which admitted the first phalanx of middle finger bloody discharge. Enlarged uterus about the size of a foetal head soft, normal fixation, no adhesions. Urine normal.

The diagnosis was erosion of the cervix metrorrhagia, and either submucous fibromyoma of the uterus or carcinoma of the body. She was carefully curetted and a pathological examination was made of the scrapings. For one week her temperature was high, but three weeks later she left the clinic cured.

Pathological report (by Prof F. Orsós)—The material for the examination consists of a mass of swollen vesicular moles embedded in clotted blood. The vesicles are of various sizes. Among these vesicle like villi there are several that are of normal thickness and type. These, upon closer examination and after longitudinal sections were made are seen to be cross sections of the processes of the vesicular villi. No normal blood filled vessels are

FIG. 1—Mass of cysts discharged per vaginam (The scale is in centimetres).

found although here and there the remnants of what might have been blood vessels can be discerned. The vesicles are in various stages of degeneration. In some the outer epithelial layer is quite normal with the nuclei staining well in some it is degenerate while in others it is entirely absent. Some have completely degenerated even in the stroma. The cells of the cyst are distended and loosened the interstices being filled with a coagulated mucous fluid. In some vesicles the outer cellular wall shows crowding and as a result of shrinkage resemble the gyri of the brain. Where the epithelial layer of the

FIG 2.—Section of scrapings from uterus

vesicle is in fairly good condition various changes can be seen: in some places the epithelial cells are low and cuboidal in others pseudo polypoid formations are present. Where the epithelium is thickened certain cells are distended forming a pseudo-lumen giving the epithelial layer a ragged appearance. The epithelial layer closely resembles the Langhans layer while the synovium is rather poorly represented (Fig 2).

A recent examination—the patient is now 65—showed the following: rectocele cystocele a senile atrophied vaginal vault, a normal small uterus, no adhesions. External os is normal.

DISCUSSION

The clinical diagnosis of these cases unless vesicles are discharged is often very difficult, especially before as well as after the menopause. Haemorrhages at this age quickly lead one to suspect malignant tumour of some sort. If the characteristic cysts are discharged there can be no doubt as to the nature of the case. Curettage is of great importance but the dangers of perforation must not be forgotten (Fromme 1909).

The prominent symptoms associated with cystic degeneration of the chorion villi are rapid increase in the size of the uterus and discharge of blood or of bloody serum.

After examining the patient one could exclude everything but the uterus as the source of the haemorrhage. One first thought of carcinoma of the body but the size and softness of the uterus could not entirely exclude fibromyoma though the infrequency of haemorrhages from a fibroid after the menopause was against it. Curettage made the diagnosis certain. No matter at what age cystic degeneration of the chorion villi occurs the patient is put out to three serious dangers—fatal haemorrhage septic infection and chorion epithelioma. In 50 per cent. of the cases chorion epithelioma develops after cystic degeneration and this is why it is important to keep the patient under close observation. It may develop even after many years but in this case it has not yet been noted. Some advocate radical treatment but the middle path is perhaps the best—close observation of the patient with bi-monthly examinations.

In my opinion there is a close connexion with the condition of the ovum. This patient's last delivery was twins at the age of 41. Another theory is that

the mole is due to inclusions of embryonic tissues that may be influenced by hormones during pregnancy. At the menopause when the influence of the pituitary gland diminishes it is possible that these changes act as an irritant to the embryonic remains causing their growth. The part played by the hormone can be explained by the fact that in 36 per cent. of the cases the mole occurs in women over 45. It is quite possible that a known hormone is responsible, but it may be that unknown hormones are the activating agents. If these should be discovered light might be thrown upon the cause of malignant tumours at this stage of life.

REPEATED PERFORATION OF A PEPTIC ULCER

WITH SUBSEQUENT TREATMENT

By A. C. LYSAGHT F.R.C.S. Eng.

CONSULTING SURGEON TO THE PONTPOOL AND DISTRICT HOSPITAL ASSISTANT SURGEON TO THE CARDIFF ROYAL INFIRMARY AND

W. BARRY WILLIAMS B.Sc., M.B. Wales

SURGEON TO THE PONTPOOL AND DISTRICT HOSPITAL

A PERFORATION of a peptic ulcer occurring more than once in the same patient is fortunately not very common. With regard to the results of patients treated by simple suture of the perforation opinion varies a great deal but in our experience the results are very good and agree with Prof. Grey Turner's¹ figures (1927) over a long series of cases in which 50 per cent. are cured and 74 per cent. are so well that they do not require further operative treatment. To have the misfortune to perforate a peptic ulcer four times in as many years must be considered extremely rare, and we therefore record a case in which this occurred with the treatment given and lessons learnt about the case.

CASE REPORT

A minor patient was aged 26 at time of first perforation. There was no previous history of importance. A sister had been treated for congenital syphilis, but his Wassermann reaction was negative and he showed none of the usual stigmata. It is of interest to note that his father died of a ruptured gastric ulcer in 1934. It is also important to record that he stoutly denied any gastric trouble whatever—dyspepsia or discomfort until his first perforation in 1932 since when he had never been free from pain or vomiting of varying intensity until his gastrectomy last year.

The first perforation occurred on Feb. 8th 1932. The patient was taken suddenly ill with acute abdominal pain at 2.30 P.M. while at work. He was admitted into the Pontpool Hospital and the perforation on the anterior wall of the pylorus was repaired by one of us (W. B. W.) the abdomen was closed with drainage.

He continued to have severe gastric symptoms in spite of medical treatment and on Sept. 14th at 3 A.M. he perforated a second time. W. B. W. once again repaired a perforation in the same situation as before and the abdomen was closed with drainage.

After this he remained fairly well for about two years and he returned to work but was never really free from dyspepsia and vomiting. He lost considerable time from work with this trouble and his doctor stated that he was always very tender in the epigastrium. These symptoms increased in intensity and on Dec. 11th 1934 a posterior no loop gastrojejunostomy was performed by a colleague. This operation did not relieve his symptoms in any way and his condition rapidly deteriorated until

¹ Turner G. G. (1927) Quoted in Rowland and Turner's "Operation of Surgery" Vol. 2 7th edit., London, 1.

on July 22nd, 1935, six months later, he perforated for the third time and was repaired by Mr Ioan Jones of Cardiff.

Once again after this, in spite of careful medical treatment, dyspepsia returned worse than ever, and he fell into a very bad state of health and the fourth perforation occurred on August 18th, 1936. The perforation was in the same situation as the previous three—the anterior wall of the pylorus—and this was repaired by Dr J P Jenkins of Pontypool.

No improvement occurred in his health after this, and he may be said to have gone from bad to worse. When seen for the first time by one of us (A C L) he appeared a thin man with an anxious expression, obviously in continuous pain, this pain was uninfluenced by diet, rest, or alkalis. He said that he was in continuous trouble, felt that another perforation was imminent, and was prepared to undergo any operation however dangerous if there was a chance of bringing about some improvement. Examination showed scars of previous operations, considerable epigastric tenderness, and obvious loss of weight, no mass could be felt. He was put on a light nutritious diet and gentle daily gastric lavage, with only slight improvement in his symptoms, and it was considered that further laparotomy was essential.

The operation on Nov. 21st, 1936, was by no means an easy one. It was performed under a combination of local and general anaesthesia. As might be expected, a lot of adhesions required dividing, when the anatomy was fully defined it was found that the spleen had become adherent to the stoma and there was a large ulcer at this situation. When the spleen was detached the stoma was opened into, it seemed as if the spleen had closed a perforation of an anastomotic ulcer. The gastrojejunostomy was undone and a wide gastrectomy then performed by the usual Polya method. Afterwards it was found that the jejunum which had been closed after detachment was very constricted, so that the operation was concluded by an entero-anastomosis. The patient made an uninterrupted recovery.

Subsequent progress—It is only three months since his last operation, so of course it is too soon to claim that he is quite cured but his progress is so satisfactory that one may hope that is so. He married on discharge from hospital. He states that for the first time for 4½ years he can eat anything without any pain, discomfort, or vomiting. His weight before the last operation was 7 st 11 lb and is now 8 st 13 lb. He says "he has never felt so well in his life, and wishes he had had the operation years ago."

The case presents the following points of interest—

(1) The complete absence of gastric or dyspeptic symptoms before his first operation in 1932, after this he was never free from trouble until his gastrectomy in 1936.

(2) The fact that his father died from a perforated peptic ulcer.

(3) The failure of the gastrojejunostomy either to ameliorate his symptoms or to prevent perforation—two of the perforations occurred after the gastrojejunostomy had been performed. At the last operation an anastomotic ulcer was found.

This is the fourth time in our experience that an anastomotic ulcer has formed in conjunction with perforation. In the previous three cases the gastrojejunostomy had been performed at the time of perforation; and in our opinion is a striking criticism of the practice of performing gastrojejunostomy at the same time as the perforation is closed.

It would be interesting to know whether patients who perforate peptic ulcers are also more prone to the formation of anastomotic ulcers if a gastrojejunostomy is performed. At any rate, it seems that if simple suture of the perforation does not cure the peptic ulcer and further, operative treatment appears necessary, gastrectomy may prove more suitable than gastrojejunostomy.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE

SECTION OF MEDICINE

At a meeting of this section on March 23rd a discussion on the

Effects on the Respiratory System of Asphyxiating Gases

was read by Dr STUART BLACKMORE of the Home Office air-raid precautions department. He confined his remarks to phosgene, since, although there was a difference of opinion in military circles as to whether lung irritants would be used in war, it was agreed that if they were used, phosgene was the most likely to be tried. Its action was not yet fully understood. Oedema of the lungs, the essential lesion was probably a direct action on the cell, perhaps caused by an alteration in the acid base equilibrium. This was certainly true of chlorine and in many of the chlorine compounds, such as phosgene, it was the chlorine element which determined toxicity. On the other hand there was the German view that the oedema was a secondary phenomenon the primary effect being on the nervous system.

Much more was known about the pathological effects produced by phosgene than about their aetiology. The main factor was lack of oxygen caused by mechanical obstruction by water in the alveoli. At an early stage a thin layer of water could be demonstrated on the alveolar epithelium and although there might be no impairment of function at that stage complete rest was needed or sudden death might result. Clinically, there were

two well defined types, the plum coloured or blue type, showing signs of CO₂ retention, and the more serious grey type in which anoxæmia predominated. The blood became very concentrated and it was worth considering whether apparatus for testing the degree of concentration of the blood might not be required on a large scale, as in cholera epidemics. The pathology of the lung lesions in mustard gas poisoning was, of course, quite different. The essential lesion here was a burn with consequent inflammation and secondary infection, no anoxæmia was present.

The one essential of treatment was oxygen. About that there was no argument. Administration could not begin too soon or go on too long. Bleeding was definitely useful in the early stages. It acted perhaps by promoting absorption of the fluid in the alveoli. Atropine had proved valueless and was contra-indicated. Opinions differed on the value of transfusion and on the solution to be used. In America urease was favoured and also emetine to cause a prolonged constriction of the capillaries. In this country, however, Barcroft had decided that transfusion had not proved of any value.

Dr R V CHRISTIE supported the German views. He suggested that the experiments of Aschoff and others in 1920 in which vagal section was shown to render an animal immune to phosgene had not been disproved. Much attention had subsequently been paid in Germany to "vagal pneumonia" and it seemed probable to him that the lung oedema was caused by irritation of the vagal nerve endings. The dyspnoea was certainly not due to anoxæmia, as a recent discussion on flying at high altitudes had shown. He believed that the Germans favoured glucose solutions for transfusion.

In answer to questions, Dr BLACKMORE regretted that in France and in this country too much emphasis had been laid on the vesicant gases to the exclusion of interest in the lung irritants. Provided the lungs were previously healthy and mustard gas could be excluded it was true that the lung irritants left no disability and produced either death or complete recovery. No fibrosis followed, in contradistinction to mustard gas. Certainly no predisposition to tuberculosis was caused. He knew of no instance of lumbar puncture being used in treatment, but thought that other drugs of the atropine group might be tried. There was no evidence that phosgene acted as a general protoplasmic poison. As regards the method of election for the administration of oxygen conservation must be kept in mind. It might have to be given for days or even weeks. He knew of a case which had recovered after two weeks continuous oxygen though in three-quarters of the fatal cases the patient died in the first 24 hours. Some sort of mechanism like the Haldane apparatus was therefore necessary which would prevent waste during expiration. It was not necessary to warm the oxygen but a reduction valve and flow metre were almost essential. The rate of administration should be from 3 litres per minute increased up to 10 litres per minute if almost immediate clinical improvement was not shown. Above 10 litres the oxygen concentration in the alveoli did not increase. It should be given for 25 minute periods with 5 minute intervals to observe the clinical effect of discontinuance. Administration of oxygen was difficult as the patients were dyspnoeic and restless and there was much expectoration and sometimes vomiting.

SECTION OF COMPARATIVE MEDICINE

At a meeting of this section on March 24th with Mr G. W. DUNCAN the president in the chair a discussion on

Nutrition and its Effect on Infectious Disease

was opened by Prof. S. J. COWELL. He pointed out the difficulty of making controlled observations on the influence of one factor alone in the nutrition of human beings. While therefore a connexion between faulty feeding and susceptibility to infectious disease had been generally admitted the evidence on which specific changes in diet had been related to definite types of infection was conflicting. Investigations of the subject had fallen into three groups. In the first, attempts were made to correlate the incidence and course of an infection with diets characteristic of different races, social groups or institutions. An example of this was Nicholls's survey in Ceylon suggesting that the malaria epidemic of 1933-34 would not have been prevented but might have been less disastrous had the masses been better fed. Other examples were Orr and Gilks's observations of two East African tribes—the one which ate mostly cereals allowed more admissions to hospital for bronchitis, tropical ulcer and malaria than the other which lived chiefly on meat, milk and raw blood—and those of Spence and M. Gonigle who separately studied the possible relation of diet to bronchitis. In the second group attempts were made to determine the effects of changes in diet on the incidence of infectious diseases both in a whole population and in isolated communities. From time immemorial famine had been thought to bring pestilence closely in its train and many held that the increased incidence of tuberculosis in Central European countries towards the end of the late war was due to the restricted diets. The

third group of observations was concerned with the part played by individual food constituents in determining resistance to infections. Severe lack of vitamin A was associated with bacterial invasion in all species of laboratory animals and the same relation had been reported in man but studies of the effect of liberal supplies of it had been inconclusive. Conflicting results had been reported by different observers of its use in puerperal infections, pneumonia, measles and common colds with perhaps a slight preponderance of evidence of benefit to colds. The speaker had observed no effect on the winter sickness rate among R.A.F. recruits nor on the occurrence of otitis media complicating scarlet fever from giving vitamin A concentrate. Such results could not be interpreted as proof that the vitamin played no part in determining the resistance of human beings to infections but suggested that dramatic effects could not be expected from giving vitamin A to patients likely to be already receiving a sufficiency.

Speaking of vitamin D Prof. Cowell said that clinicians recognised the tendency of children with rickets to develop bronchitis and pneumonia though in one or two careful studies pneumonia had been found to attack as many children with well calcified bones as with radiological evidence of rickets. The mechanical obstruction to respiration provided by a deformed and yielding chest wall might explain in part the tendency generally believed to exist of ricketty children to succumb to pneumonia. Vitamins B and C had each been put forward as preventives of infection and iron deficiency had been shown by Dr Helen Mackay to be associated with high incidence of infection of the respiratory tract in infants. The speaker felt that good nutrition was more likely to determine the course an infection would take than whether infection would occur. The available evidence relating to man so far did not warrant the view that one isolated food constituent was responsible in any specific way for maintaining the body's resistance to infection. It was possible that an optimum state of nutrition lasting for a longer period of life than had been aimed at in most tests was necessary to secure the maximum degree of resistance to infection.

Miss HARRIETTE CHICK, D.Sc., pointed out that the variables influencing incidence of infection included besides the state of nutrition the dosage of infection, the virulence and such factors as chill, fatigue and anxiety. In any acute epidemic these other variables had the greater influence having a wide range of variation and only a short time to work in; they were relatively less important in slow chronic conditions. The state of nutrition was more likely to be important in determining the course and sequelae of infections than their incidence, thus influenza or measles might run through a public school as quickly as through a school whose children received a diet which was deficient according to modern standards. The severity of the 1918 influenza epidemic might have been due to the poor state of nutrition. Dr Chick then gave two examples of chronic disease apparently influenced by nutrition: the first was the infective conjunctivitis which a few decades ago had been widespread among poor children (though never among the better-to-do) but was now extinct. The second example was the incidence of tuberculosis in two parts of Austria; between the years 1913 and 1919 the deaths from tuberculosis remained almost constant in Salzburg a rural area getting plenty of butter and meat whereas in Vienna where the diet was poor quantitatively and qualitatively at the end of the war the deaths had nearly doubled. It seemed

on July 22nd, 1935, six months later, he perforated for the third time and was repaired by Mr Ioan Jones of Cardiff.

Once again after this, in spite of careful medical treatment, dyspepsia returned worse than ever, and he fell into a very bad state of health and the fourth perforation occurred on August 18th 1936. The perforation was in the same situation as the previous three—the anterior wall of the pylorus—and this was repaired by Dr J P Jenkins of Pontypool.

No improvement occurred in his health after this, and he may be said to have gone from bad to worse. When seen for the first time by one of us (A C L) he appeared a thin man with an anxious expression, obviously in continuous pain, this pain was uninfluenced by diet, rest, or alkalis. He said that he was in continuous trouble, felt that another perforation was imminent, and was prepared to undergo any operation however dangerous if there was a chance of bringing about some improvement. Examination showed scars of previous operations, considerable epigastric tenderness, and obvious loss of weight, no mass could be felt. He was put on a light nutritious diet and gentle daily gastric lavage, with only slight improvement in his symptoms, and it was considered that further laparotomy was essential.

The operation on Nov 21st, 1936, was by no means an easy one. It was performed under a combination of local and general anaesthesia. As might be expected, a lot of adhesions required dividing, when the anatomy was fully defined it was found that the spleen had become adherent to the stoma and there was a large ulcer at this situation. When the spleen was detached the stoma was opened into, it seemed as if the spleen had closed a perforation of an anastomotic ulcer. The gastrojejunostomy was undone and a wide gastrectomy then performed by the usual Polya method. Afterwards it was found that the jejunum which had been closed after detachment was very constricted, so that the operation was concluded by an enteroanastomosis. The patient made an uninterrupted recovery.

Subsequent progress—It is only three months since his last operation, so of course it is too soon to claim that he is quite cured, but his progress is so satisfactory that one may hope that is so. He married on discharge from hospital. He states that for the first time for 4½ years he can eat anything without any pain, discomfort, or vomiting. His weight before the last operation was 7 st 11 lb and is now 8 st 13 lb. He says 'he has never felt so well in his life, and wishes he had had the operation years ago.'

The case presents the following points of interest—

(1) The complete absence of gastric or dyspeptic symptoms before his first operation in 1932 after this he was never free from trouble until his gastrectomy in 1936.

(2) The fact that his father died from a perforated peptic ulcer.

(3) The failure of the gastrojejunostomy either to ameliorate his symptoms or to prevent perforation—two of the perforations occurred after the gastrojejunostomy had been performed. At the last operation an anastomotic ulcer was found.

This is the fourth time in our experience that an anastomotic ulcer has formed in conjunction with perforation. In the previous three cases the gastrojejunostomy had been performed at the time of perforation, and in our opinion is a striking criticism of the practice of performing gastrojejunostomy at the same time as the perforation is closed.

It would be interesting to know whether patients who perforate peptic ulcers are also more prone to the formation of anastomotic ulcers if a gastrojejunostomy is performed. At any rate, it seems that if simple suture of the perforation does not cure the peptic ulcer and further, operative treatment appears necessary, gastrectomy may prove more suitable than gastrojejunostomy.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE

SECTION OF MEDICINE

At a meeting of this section on March 23rd a discussion on the

Effects on the Respiratory System of Asphyxiating Gases

was read by Dr STUART BLACKMORE of the Home Office air raid precautions department. He confined his remarks to phosgene, since, although there was a difference of opinion in military circles as to whether lung irritants would be used in war, it was agreed that if they were used, phosgene was the most likely to be tried. Its action was not yet fully understood. Oedema of the lungs, the essential lesion, was probably a direct action on the cell, perhaps caused by an alteration in the acid base equilibrium. This was certainly true of chlorine and in many of the chlorine compounds, such as phosgene it was the chlorine element which determined toxicity. On the other hand there was the German view that the oedema was a secondary phenomenon, the primary effect being on the nervous system.

Much more was known about the pathological effects produced by phosgene than about their aetiology. The main factor was lack of oxygen caused by mechanical obstruction by water in the alveoli. At an early stage a thin layer of water could be demonstrated on the alveolar epithelium and although there might be no impairment of function at that stage complete rest was needed or sudden death might result. Clinically, there were

two well defined types, the plum coloured or blue type, showing signs of CO₂ retention, and the more serious grey type in which anoxæmia predominated. The blood became very concentrated and it was worth considering whether apparatus for testing the degree of concentration of the blood might not be required on a large scale, as in cholera epidemics. The pathology of the lung lesions in mustard gas poisoning was, of course, quite different. The essential lesion here was a burn with consequent inflammation and secondary infection, no anoxæmia was present.

The one essential of treatment was oxygen. About that there was no argument. Administration could not begin too soon or go on too long. Bleeding was definitely useful in the early stages, it acted perhaps by promoting absorption of the fluid in the alveoli. Atropine had proved valueless and was contra indicated. Opinions differed on the value of transfusion and on the solution to be used. In America urease was favoured and also emetine to cause a prolonged constriction of the capillaries. In this country, however, Barcroft had decided that transfusion had not proved of any value.

Dr R V CHRISTIE supported the German views. He suggested that the experiments of Aschoff and others in 1920 in which vaginal section was shown to render an animal immune to phosgene had not been disproved. Much attention had subsequently been paid in Germany to 'vagal pneumonia' and it seemed probable to him that the lung oedema was caused by irritation of the vagal nerve endings. The dyspnoea was certainly not due to anoxæmia, as a recent discussion on flying at high altitudes had shown. He believed that the Germans favoured glucose solutions for transfusion.

In answer to questions Dr BLACKMORE regretted that in France and in this country too much emphasis had been laid on the vesicant gases, to the exclusion of interest in the lung irritants. Provided the lungs were previously healthy and mustard gas could be excluded, it was true that the lung irritants left no disability and produced either death or complete recovery. No fibrosis followed in contradistinction to mustard gas. Certainly no predisposition to tuberculosis was caused. He knew of no instance of lumbar puncture being used in treatment but thought that other drugs of the atropine group might be tried. There was no evidence that phosgene acted as a general protoplasmic poison. As regards the method of election for the administration of oxygen conservation must be kept in mind. It might have to be given for days or even weeks. He knew of a case which had recovered after two weeks continuous oxygen though in three quarters of the fatal cases the patient died in the first 24 hours. Some sort of mechanism like the Haldane apparatus was therefore necessary which would prevent waste during expiration. It was not necessary to warm the oxygen but a reduction valve and flow metre were almost essential. The rate of administration should be from 3 litres per minute increased up to 10 litres per minute if almost immediate clinical improvement was not shown. Above 10 litres the oxygen concentration in the alveoli did not increase. It should be given for 25 minute periods with 5 minute intervals to observe the clinical effect of discontinuance. Administration of oxygen was difficult as the patients were dyspnoeic and restless and there was much expectoration and sometimes vomiting.

SECTION OF COMPARATIVE MEDICINE

At a meeting of this section on March 24th with Mr G W DUNCAN the president, in the chair a discussion on

Nutrition and its Effect on Infectious Disease

was opened by Prof S J COWELL. He pointed out the difficulty of making controlled observations on the influence of one factor alone in the nutrition of human beings. While therefore, a connexion between faulty feeding and susceptibility to infectious disease had been generally admitted, the evidence on which specific changes in diet had been related to definite types of infection was conflicting. Investigations of the subject had fallen into three groups. In the first attempts were made to correlate the incidence and course of an infection with diets characteristic of different races, social groups or institutions; an example of this was Nicholls's survey in Ceylon suggesting that the malaria epidemic of 1933-34 would not have been prevented but might have been less disastrous had the masses been better fed. Other examples were Orr and Gilks's observations of two East African tribes—the one which ate mostly cereals showed more admissions to hospital for bronchitis, tropical ulcer and malaria than the other which lived chiefly on meat, milk and raw blood—and those of Spence and Mc Gonigle who separately studied the possible relation of diet to bronchitis. In the second group attempts were made to determine the effects of changes in diet on the incidence of infectious diseases both in a whole population and in isolated communities. From time immemorial famine had been thought to bring pestilence closely in its train and many held that the increased incidence of tuberculosis in Central European countries towards the end of the late war was due to the restricted diets. The

third group of observations was concerned with the part played by individual food constituents in determining resistance to infections. Severe lack of vitamin A was associated with bacterial invasion in all species of laboratory animals and the same relation had been reported in man but studies of the effect of liberal supplies of it had been inconclusive. Conflicting results had been reported by different observers of its use in puerperal infections, pneumonia, measles and common colds with perhaps a slight preponderance of evidence of benefit to colds. The speaker had observed no effect on the winter sickness rate among R.A.F. recruits nor on the occurrence of otitis media complicating scarlet fever from giving vitamin A concentrate. Such results could not be interpreted as proof that the vitamin played no part in determining the resistance of human beings to infections but suggested that dramatic effects could not be expected from giving vitamin A to patients likely to be already receiving a sufficiency.

Speaking of vitamin D Prof. Cowell said that clinicians recognised the tendency of children with rickets to develop bronchitis and pneumonia, though in one or two careful studies pneumonia had been found to attack as many children with well-calcified bones as with radiological evidence of rickets. The mechanical obstruction to respiration provided by a deformed and yielding chest wall might explain in part the tendency generally believed to exist of rickety children to succumb to pneumonia. Vitamins B and C had each been put forward as preventives of infection and iron deficiency had been shown by Dr Helen Mackay to be associated with high incidence of infection of the respiratory tract in infants. The speaker felt that good nutrition was more likely to determine the course an infection would take than whether infection would occur. The available evidence relating to man so far did not warrant the view that one isolated food constituent was responsible in any specific way for maintaining the body's resistance to infection. It was possible that an optimum state of nutrition lasting for a longer period of life than had been aimed at in most tests was necessary to secure the maximum degree of resistance to infection.

Mrs HARRIETTE CHICK, D.Sc., pointed out that the variables influencing incidence of infection included besides the state of nutrition the dosage of infection, the virulence and such factors as chill, fatigue and anxiety. In any acute epidemic these other variables had the greater influence having a wide range of variation and only a short time to work in they were relatively less important in slow chronic conditions. The state of nutrition was more likely to be important in determining the course and sequelae of infections than their incidence, thus influenza or measles might run through a public school as quickly as through a school whose children received a diet which was deficient according to modern standards. The severity of the 1918 influenza epidemic might have been due to the poor state of nutrition. Dr Chick then gave two examples of chronic disease apparently influenced by nutrition, the first was the infective conjunctivitis which a few decades ago had been widespread among poor children (though never among the better to do) but was now extinct. The second example was the incidence of tuberculosis in two parts of Austria; between the years 1913 and 1919 the deaths from tuberculosis remained almost constant in Salzburg a rural area getting plenty of butter and meat whereas in Vienna where the diet was poor quantitatively and qualitatively at the end of the war the deaths had nearly doubled. It seemed

that resistance to infection might be affected by diet while susceptibility was not. Under properly controlled experimental conditions any one specific food factor could be an anti-infective agent, be it iron or vitamin A, but as most infections entered by the nasopharynx, animals suffering from deficiency of vitamin A were particularly susceptible. Dr Chick then described some unpublished experiments carried out with Sir Charles Martin and Dr Bird at Cambridge. They had produced in pigs an intestinal condition resembling a disease of maize eating humans. The pigs received one of three diets: one consisted mostly of maize, in the second the maize was replaced by wheat and barley, in the third yeast was added to the maize diet. Those on the maize alone died, after 8 or 9 weeks, of an infection of the caecum and colon; those on the second diet developed diarrhoea but eventually pulled through; the third group grew rather faster than ordinary pigs. Apparently there was either some latent infection which could only manifest itself when the diet was deficient, or some organism ordinarily non-pathogenic which was then able to invade the tissues. All attempts to isolate the organism had failed. The factor in the yeast rendering the diet satisfactory was water soluble and heat stable and was the anti-infective vitamin to that particular condition; its relation to the vitamin B₂ complex had not been determined.

Mr LESLIE HARRIS, Sc D, said that the excretion of vitamin C normally depended on the intake in the diet; in controlled humans however the excretion suddenly dropped when the subject had a cold or influenza. It normally increased after a test dose but failed to do so in scorbutic children. He had been examining the excretion in infective conditions and found that it was decreased in acute rheumatism in childhood and in tuberculous infection, even during convalescence cases of acute rheumatism continued to excrete reduced quantities, and this finding seemed to tally with the clinical fact that the convalescent children were liable to relapse. Infective conditions apparently reduced the saturation of the tissues to vitamin C, so that patients even when receiving ample supplies excreted it at a lower level than the controls, and the lowered secretion might have some diagnostic value. The question remained whether vitamin C deficiency was the result of fever or the cause of infection. The speaker had estimated the vitamin C content of the tissues and the suprarenals of guinea pigs infected with tuberculosis and had found the content much lower than in the tissues of normal animals; it appeared that the vitamin had been taken up by the tissues. It was certain that deficiency of that vitamin reduced the resistance of guinea pigs to infection and many workers agreed that similar effects were observed in man. If it played some specific part in defence this might be that it was required by formative cells for in its absence scar tissue and hair failed to form. It had also been suggested that it played a part in the formation of blood cells and antibodies, as a high concentration had been found in leucocytes; the theory that it was concerned in antibody formation was plausible but so far treatment by vitamin C dosage had been disappointing.

Mr J. T. EDWARDS, D Sc, spoke of the effects of nutrition in foot and mouth disease. He had been working with rats and had found that the better nourished animals were more susceptible to the disease. Further work had shown that the addition of raw liver and carrot to a diet increased the susceptibility and that the less susceptible animals were definitely

anaemic. Hedgehogs which were very liable to catch the infection did not do so when hibernating. It seemed then that the susceptibility depended partly on increased metabolism rather than on one specific factor. These findings had their parallel in veterinary experience, for animals seemed particularly prone to contract foot and mouth disease when in prime condition and at the prime of life.

Mr H. H. GREEN, D Sc, said that malnourishment was generally believed to predispose to helminth infection. Definite experimental evidence was difficult to obtain on the subject but in one series of experiments poorly nourished animals had shown a greater capacity to produce helminth eggs.

Dr D. F. C. WILSON described how she had investigated 2000 children of different creeds in the Punjab and had come to the conclusion that there was no very definite relation between food deficiency and malaria.

Dr WARREN CROWE said he had produced experimental arthritis in the rabbit by injection of strains of streptococci and had found that those of his animals receiving a diet deficient in vitamins did not develop arthritis, whereas those on full diets did. He suggested that the arthritis was a disease of reaction to a noxious agent, if the animal were sufficiently weakened by poor diet there was no reaction. This conjecture was supported clinically, for patients after lying in bed with arthritis often complained that the pain was worse, although they were really better. A parallel might be found, he thought, in the post-mortem findings of officers dying of influenza in 1918, those who died had often been "fighting fit" and only ill two days, they died of drowning from their own reaction.

Mr A. L. BACHARACH thought that all constituents of diet might play an anti-infective part but that together they acted not as their sum but by integration. Resistance might depend on two factors, but the effect of lack of one only be shown when the other was lacking too. He mentioned that vitamin C excretion was reduced in benzene poisoning, pregnancy and lactation, and that any theory to explain the reduced excretion in fever should also explain it in those conditions. He thought that the benefit of giving ascorbic acid might not be shown during the course of one illness, but might build up the reserves for the next.

Dr HARRIS supposed that the increased activity and demands on the body during pregnancy and lactation might explain the reduced excretion in those conditions.

LIVERPOOL MEDICAL INSTITUTION

At a pathological meeting of this institution on March 11th, with Mr R. KENNON in the chair, a paper on the

Pathological Aspects of Criminal Abortion

was read by Dr W. H. GRACE. He pointed out that the Offences against the Person Act used only the word "miscarriage," meaning the emptying of the uterus at any stage of the pregnancy, and made no attempt to define the word "unlawfully" or to define "lawful" emptying of the uterus, moreover there was no difference in the nature of the crime if the uterus did not contain the products of conception. Death following criminal abortion was usually either (1) quick, being often due to shock, and more rarely to air embolism, or (2) delayed, due to sepsis. The abortionist was more likely to be caught if death

was rapid. The methods of procuring criminal abortion were (1) violence applied generally, including rolling downstairs and kneading or compressing the abdomen; (2) internal administration of drugs on which Dr Grace remarked that there is no drug and no combination of drugs which when taken by the mouth will cause a healthy uterus to empty itself unless it be given in doses sufficiently large to endanger seriously by poisoning the life of the woman who takes it and (3) mechanical injuries to the uterus and its contents either by uterine sounds catheters wire pieces of wood umbrellae ribs, hairpins, penholders and the like or by injection of fluids such as solutions of soap or sodium bicarbonate. In describing his method of examination in cases of suspected criminal abortion Dr Grace emphasised the importance of keeping all objects and organs which might be used as evidence.

Dr E CHOMIN LOWE spoke of the difficulty often met with in cases in which death followed self attempted abortion. Frequently there was no evidence of damage to uterus, cervix or vagina, and death had apparently resulted from shock. It was important as Dr Grace had said to collect any fluid in the vagina for sometimes this provided the only evidence of attempted interference. He thought that right-sided pelvic infection should arouse suspicion of interference by mechanical means probably carried out by someone other than the deceased.

Dr W A. MACKAY speaking of the relation between medicine and the law said that doctors were in no sense criminal detectives and when abortion was suspected usually nothing should be done. In case of death however information to the police became a duty.

Mr M DATNOW pointed out that general violence as a cause of abortion must include the associated shock and fright for often severe physical injury did not disturb pregnancy. In experiments on animals he had used many of the well known abortifacient drugs but had never succeeded in bringing about abortion in fact some actually tended to prolong the period of pregnancy. An exception was lead which almost always produced abortion. Mr Datnow did not think that injection of fluids would bring about abortion unless the fluid was injected into the uterine cavity. He drew attention to certain soap pastes which were being extensively used on the Continent to bring about abortion therapeutically.

Mr C H WALSH stated that in his opinion criminal abortion was on the increase. A favourite method was the use of intra uterine injection which left little or no trace whether of trauma or of incriminating material. He agreed with Dr Grace that there was no known drug taken by mouth which would procure abortion without disabling or killing the mother. He instanced the death of a woman lately admitted to hospital moribund as the result of taking an overdose of the female pills so consistently and largely advertised in the daily press.

Congenital Microcolon

Dr W E COOKE and Dr G RONALD ELLIS said that congenital narrowing or obliteration of the intestines was rare and that the incidence of congenital microcolon appeared to be less than 1 in 522 802 post mortems. They had however encountered 2 cases within six months. Both were in males.

The only symptom was vomiting and the condition was diagnosed at exploratory laparotomy. The rectum was examined before operation and was found to be normal in each case. Post mortem the duodenum and jejunum

were empty and flaccid, and the ileum distended with inspissated meconium. Towards the cecum the ileum became less distended. The cecum contained a little meconium but the contents were chiefly cell debris. The colon and in fact the whole canal was patent throughout. The colon contained cell debris but no meconium. No peritoneal bands were present. Microscopically the duodenum and jejunum appeared stretched but the walls and lymphoid tissue seemed normal. The muscular coat of the ileum was hypertrophied. The mucous membrane of the colon was normal but the muscular coat was hypertrophied. In one case the gut had rotated and the colon was in the normal position. In the other the gut had not rotated and the whole of the colon was on the right side.

Many theories had been propounded to explain the condition including peritoneal bands absence of vis a tergo occlusion of the bowel lumen and want of patency of the ileocecal valve and insufficient blood-supply. The probable explanation however lay in defective nerve-supply anatomically the colon was normal. The nerve-supply of the colon from the ileocecal valve onwards to its junction with the rectum obtained its motor fibres from the pelvic visceral nerve (the sacral division of the parasympathetic) and the inhibitory fibres from the inferior mesenteric ganglion (sympathetic). The condition was a lack of relaxation—an achilasia. As Greig suggested the anatomical structure was perfect but the meconium had passed so far and no further because the next segment—in this case the cecum—had never opened to receive it.

Tuberculous Kidney with Giant Ureter

Mr A S KERR and Mr KENNON showed a kidney which was almost entirely replaced by tuberculous caseous material removed from a woman aged 34.

She had had urethral pain and extreme frequency of micturition for two years. There was no hæmaturia but the urine contained thick pus in which many tubercle bacilli were found. On cystoscopy the bladder held only two ounces and the mucosa was much congested. The right ureteric orifice was raised and congested and there were bulles around it. The left orifice appeared normal. Intravenous indigo-carmin was excreted from the left side in good concentration in 4½ minutes but none was seen from the right side in 15 minutes. Uroasclectan showed normal function and appearance on the left side but no dye was excreted by the right kidney. A sample of urine removed from the left kidney by ureteric catheterisation was found to be free from tubercle bacilli. Nephrectomy was therefore performed and it was noticed at operation that the lower four inches of the ureter were enormously dilated and thickened compared with the pencil like upper four to five inches. As much as possible of the ureter was therefore removed.

The interest of the specimen lay partly in the great dilatation in the lower part of the ureter and partly in the fact that within three weeks of the operation the patient was able to retain urine for periods up to four hours and had passed as much as 10 oz in a single act of micturition. The question arose whether the ureteric dilatation was due to destruction of the ureteric orifice and reflux of urine from the bladder or to stenosis of the orifice and excessive internal ureteric pressure. The very rapid reduction in frequency of micturition suggested that there might have been a reflex arc between the diseased kidney and the micturition centres.

Mr CHARLES WELLS said he thought that tuberculous kidney was often associated with dilatation of the ureter. This could be followed in X ray pictures down to the level of the bladder where there was usually a gap between the ureteric and the bladder shadows. This gap was due to the thickness of the

bladder wall and there was little doubt that it was obstruction at the bladder wall which caused the dilatation. This obstruction was first due to spasm and later to fibrosis, which might in time lead to complete occlusion of the orifice. The recognition of spasm as a factor was important because the healthy kidney might often have a dilated ureter from this cause and the existence of dilatation of the ureter alone was, therefore, not a safe criterion of tuberculosis of the corresponding kidney. In treatment the recognition of a dilated ureter was necessary because all such ureters needed to be removed together with the kidney. Nephro-ureterectomy took very little longer than simple nephrectomy and had two strong points to recommend it. First, the removal of the whole of the source of tuberculous

material gave the bladder a very much better chance of rapid convalescence, and secondly, the risk of sinus formation in the wound was greatly diminished. It seemed likely that patients suffering from persistent sinus did so for exactly the reason that they had dilated ureters obstructed at the level of the bladder capable, therefore, of discharging only upwards through the wound.

Mr KERR, Prof R E KELLY, and Mr KENNON reported two cases of *post anal dermoid* and Mr KERR and Mr KENNON a case of *suprasternal dermoid*. Dr T F HEWER and Dr DOUGLAS BIGLAND described a case of *subarachnoid hamorrhage from the circle of Willis*, and Dr ELLIS one of *cerebral abscess associated with bronchiectasis*.

REVIEWS AND NOTICES OF BOOKS

The Public Health Act, 1936

By DAVID J BEATTIE, LL.M., Assistant Solicitor to the Beckenham Corporation. London: Solicitors' Law Stationery Society Ltd. 1937. Pp 503. 40s.

THE vast new Public Health Act, which rewrites the health provisions affecting England outside London, will come into force next October. Those who are accustomed to the geography of the old Acts which it supersedes will have to learn their way afresh. Mr Beattie's book will be found an excellent guide. The case law, so far as applicable for the elucidation of clauses which now reappear in a new context, is faithfully set out. A particularly useful feature is the comparative table which shows in parallel columns the references to repealed enactments and their present equivalents. The departmental committee which reported on the consolidation of enactments relating in the first place to local authorities and local government, and in the second to public health have built themselves an abiding monument in the Acts of 1933 and 1936. As Sir Gwilym Gibbon points out in his foreword to Mr Beattie's book, these Acts represent a new legislative technique. A committee of experts was equipped with a Treasury draftsman. Its draft Bill was not pure consolidation, there was substantial amendment though not of a controversial kind. Judicious changes were made in the course of rendering the old laws more simple, uniform, and concise. These changes were not effected by a separate amending Bill. The committee thus ran the risk, in combining consolidation with amendment, of exposing its draft Bill to the copious and sporadic amendments which private Members of Parliament might casually seek to insert. Fortunately the private Members behaved with noble self-control, and the Bill on which such devotion had been lavished was allowed to pass into law with remarkable swiftness. It is not entirely convenient that separate health codes should exist for London and for the rest of England when there is so much common ground. Part 10 of the new Act (dealing with canal boats) is expressly applied to London. On the other hand the parts dealing with baths and washhouses, with infant life protection, and with the registration of nursing homes have to be duplicated in the parallel new Public Health (London) Act. Some will think that more might have been done to keep the metropolis and the provinces in line. The drafting of the two codes seems to have been by different hands, nor

did one hand always know what the other hand was doing. Thus, when the Public Health Act repealed a number of specified enactments, it was apparently necessary to provide that if any of the repealed enactments were wholly or partly re-enacted in the Public Health (London) Act (which received the Royal Assent on the same day), an Order in Council might declare certain passages in the new Public Health (London) Act to be equivalent to those repealed enactments, and thereupon those passages in the Public Health (London) Act would be repealed too. In the last few days an Order in Council has appeared. This method of legislation may be watertight but nobody can pretend that it makes things easy for the layman. This, however, is not a matter to be blamed on Mr Beattie who has done all he could to enlighten us about the law as it will be next October.

1 Nutritional Factors in Disease

By WILLIAM ROBERT FEARON, M.B., Sc.D., F.I.C. London: William Heinemann (Medical Books) Ltd. 1936. Pp 141. 7s. 6d.

2 Normal Diet and Healthful Living

By W. D. SANSUM, M.D., Chief of the Staff of the Sansum Clinic, Santa Barbara, California, R. A. HARE, M.D., Member of the Staff of the Clinic, and RUTH BOWDEN, B.S., Dietitian of the Clinic. London: Macmillan and Co., Ltd. 1936. Pp 243. 8s. 6d.

1 THIS is an essay which gained for its author the Buckston Browne prize awarded by the Harveian Society of London in 1935. It would be unfair to criticise because it fails as a somewhat superficial survey of a subject which could not be properly dealt with in less than several volumes. At the same time it is difficult to escape the feeling that the author has attempted both too much and too little, for example, the discussion (p. 45) of the relation of protein excess to nephritis is less of a summary than a brief set of references to a series of somewhat contradictory papers. Throughout this essay we have been unable to discover any clear outline of the important conception of conditioned deficiency diseases in which a normal diet fails to give proper nutrition owing to some failure by the body to assimilate or utilise essential food factors. It is the absence of any discussion of this conception that makes us dubious of the author's rationale for his conclusion that there are three main determining factors of nutritional disorder: inherited constitution, physiological strain, and conditions of modern civilisation.

2 The authors of this book have made a practice of discussing questions of nutrition with groups of their patients and have therefore acquired skill in describing the known scientific facts in terms understandable by the layman. They are doubtless justified in their belief that much good has resulted to the patients as a consequence of this education and they have set out here the main facts which their experience leads them to believe should be emphasised in such discussions. Even at a time when far too many books of doubtful value are appearing on questions of diet this one can be recommended as eminently sound.

Bainbridge and Menzies' Essentials of Physiology

Eighth edition. Edited and revised by H. HARRIMON, M.D. So D. M.R.C.P. F.R.S. Professor of Physiology University of London at St. Bartholomew's Medical College. London: Longmans Green and Co. Ltd. 1936. Pp. 651. 14s.

In the preface we read that new chapters have been written on the nutrition of the heart, on the oxygen-carrying power of the blood, on the vitamins on tissue oxidation, on synapses and on pregnancy and parturition. Additional paragraphs have been inserted in many other chapters. The editor has preserved the original design of the work which consists of sixty short chapters chopped into sub-divisions; these rarely consist of more than one paragraph each of the paragraphs having a heading of heavy black type. The length of the paragraphs is the only indication of their relative importance. To the experienced physiologist the book reads rather like a newspaper and does not seem ideally arranged for learning. But a considerable proportion of students have shown that it meets their needs and by some of them in every generation. Bainbridge and Menzies is regarded as a kind of testament. The facts of physiology are to be found in it briefly stated, stripped of much that lends them interest in more leisurely treatises, but undeniably present. There is a type of mind—and here no criticism is implied—which feels safer when adding to its knowledge brick by brick and making certain that each brick is in place before adding the next. The size or importance of the brick does not matter; that is the architect's business. It is sufficient to know that if each one has been faithfully laid in its place the finished structure must be reasonably stable. Bainbridge and Menzies is probably the only English text book which presents physiology in a form suitable for such students and therefore has its own niche. Moreover there must be a large number of students who have studied a larger book who will find it invaluable for revision purposes. If the historical reasoning which lies behind it but finds little place in it, is understood it becomes an excellent manual for reference.

Alltagsorthopädie des Praktischen Arztes

By Regierungsrat Dozent Dr. SIEGFRIED ROMICH. Wien: Aesculap-Vorlag. 1936. Pp. 69. M.2.70.

This little book sets out to cover in 50 pages the whole field of orthopaedic practice as it affects the general practitioner. It is surprising that the attempt should have succeeded to such a measure. In a short introduction Prof. Spitzzy points out that while each specialist has leisure to play in his own backyard

ephemeral controversies have little interest for the general practitioner what he wants is undisputed facts of practical value. He is provided here with insight into the nature of orthopaedic conditions and into the difficulties that are likely to be encountered in their treatment as well as with suggestions for simple measures to which the commoner types respond. For example the author shows that functional inefficiency depends not only on the structure of the organ but also on the ratio of the demands made on it to its inherent strength, a point frequently overlooked in practice. Either the low arched foot or the cavus foot may become painful when subject to excessive strain but each needs a different type of shoe and height of heel. Arthrosis deformans, again the non-infective form of joint disease due to slow wearing out of the joint tissues, will develop in any patient who lives long enough but may occur in early adult life as the result of abnormal strain as in an unreduced congenital dislocation. In regard to hallux valgus the author reminds us that this is always a symptom of flat foot, and protests that the fashion of putting such minor operations as its correction at the end of a long list and leaving them to an inexperienced operator accounts for some at least of the unsatisfactory results obtained. The surgeon tends to forget that what is minor to him is a major disability to the patient. In connection with surgical tuberculosis the wise observation is made that all these cases run a natural course of invasion and healing which can be modified but not reversed by treatment; the measures applied in the first stage may diminish but will not eliminate tissue destruction while any form of treatment applied during regression is likely to acquire more credit than it deserves.

In the final chapter on plaster of Paris the modern controversy on the relative merits of padded and unpadded plasters is disposed of by the shrewd comment that both are bad when badly applied while either is efficient in expert hands. Prof. Spitzzy emphasises the part which general practitioners can play in the early diagnosis of crippling conditions and in directing them to centres for efficient treatment while he reminds us of the economic importance of flat foot and rheumatism as sources of disability in the working-class population even amongst adolescents. An English translation of these crisp pithy chapters would be welcome.

Cunningham's Text-book of Anatomy

Seventh edition. Edited by J. C. BRASH, M.A. M.D. F.R.C.S. Edin. Professor of Anatomy University of Edinburgh and E. B. JAMISON, M.D. Lecturer on Anatomy in the University. London: Humphrey Milford Oxford University Press. 1937. Pp. 1596. 42s.

SOME years have gone by since the last issue of this famous text book saw the light. In the interval Prof. Robinson has retired from the chair of anatomy at Edinburgh; this edition is in the joint charge of his successor and his experienced senior assistant. The book is now produced in the new English (B 1) revised terminology and is thus in line with the latest anatomical treatises. Since the list of contributors was printed we observe that two of them have died: Prof. Francis Dixon and Sir Grafton Elliot Smith, the former after he had finished his revision of the classical section on the urogenital system. The section on the central nervous system from the masterly pen of Sir Grafton Elliot Smith remains as a monument

to his erudition, with some little additions and alterations made by him and others by his associates, Dr Una Fielding and Prof A Durward. Most of the contributors to this edition are new, and they have reason to be proud of the book they have produced, it is a great work, worthy of the place "big Cunningham" occupies in the forefront of anatomical literature. Much added material in the text and several figures and radiograms have been included in a book which, in some indefinable way, seems less formal than its predecessors in the treatment of matters anatomical, and this is all to the good.

Synopsis of Surgical Anatomy

Third edition By ALEXANDER LEE MCGREGOR, MCh Edin, FRCS Eng, Lecturer on Surgical Anatomy, University of Witwatersrand, Assistant Surgeon, Johannesburg General Hospital, Bristol John Wright and Sons, Ltd, London Simpkin Marshall Ltd 1936 Pp 664 17s 6d

CERTAIN additions and changes have been made in this third edition, and the general character of this excellent little book maintains a high standard. We would like to see some notice taken of the sexual difference in ossification times and fusions, and indeed in some other respects, but that is the only criticism we can make.

Modern Discoveries in Medical Psychology

By CLIFFORD ALLEN, MD, MRCP, DPM, Psychotherapist to the Institute of Medical Psychology London Macmillan and Co, Ltd 1937 Pp 279 8s 6d

THE author of this introduction to modern psychological medicine has systematised his exposition by showing the progress of psychopathology through the history of the personalities who have made the leading discoveries. Mesmer and the work of his followers, Liebaux and others, are first considered in relation to hypnosis. The contributions of Janet and Morton Prince to the structure of the mind show us how the modern theories of the unconscious were made clear in the study of hysteria and multiple personalities. Neither of these celebrated clinicians went beyond superficial analysis of personality, and their treatment was largely suggestion and hypnosis with a view to reintegration. Prince, however, is shown as preparing the ground for an understanding of Freud inasmuch as he recognised the importance of emotional disturbances as precipitating factors. Freud naturally comes in for the lion's share of the book and a mead of praise which could only have been given by an ardent devotee whose exposition is however simple and accurate. Alfred Adler and C G Jung do not arouse Dr Allen's admiration. The former is regarded as superficial and his organ jargon as nothing more than an extension and perhaps an exaggeration of a Freudian concept. Jung's theory of types and his concept of the collective unconscious receive proper attention but are perhaps rather too easily dismissed as tending to mysticism. Kretschmer's theories on the relation of body and mind and their connexion with clinical types are treated somewhat superficially. The book closes with an appreciation of Pavlov which is warmer than one would have expected. Pavlov and Freud are made to stand out as the two great figures in modern clinical psychology. Both have their roots in biology, and their divergences would appear to be due to

little more than differences of language expressing ultimately the same Determinism.

This is a volume that can be safely placed in the hands of the student of psychopathology provided that his critical faculties will not be blinded by the bright light of the author's partisan enthusiasm.

Common Sense and Psychology

By ALAN MABERLY, M.A., M.B. London Frederick Muller 1936 Pp 160 5s

Dr Maberly has contracted into a small space a considerable amount of information regarding modern theories of psychology with particular regard to the personality and his disturbances. In a brief space he attempts, however in a popular fashion, to explain mental mechanisms, the significance of sex, and the relationship of parent to child. Common sense is certainly the mainspring of this book, and the author has in large measure succeeded in avoiding the complexities of modern theories. Unfortunately in the last chapter, which deals with fear and guilt, he has not been very successful in coming to grips with this central problem of modern psychopathology.

The book could be read with profit by an intelligent layman, and by doctors who have so far not taken much interest in medical psychology.

Allergic Diseases

Their Diagnosis and Treatment Fourth edition By RAY M. BALYEAT, M.A., MD, FACP, Associate Professor of Medicine and Lecturer on Diseases due to Allergy, University of Oklahoma Medical School. Assisted by RALPH BOWEN, B.A., MD, P.A.A.P. Philadelphia F A Davis Co 1936 Pp 516 5s 6d

THE physician studying allergy is apt to be appalled by the complexity of the subject, and perhaps dismayed by a certain lack of precision, though not always of confidence, when he consults the expert. He may wonder how much he may rely for instance on such methods as skin testing, or on trial diets in the detection and elimination of allergens. Dr Balyeat's book offers him a full account of this difficult subject, copiously illustrated by pictures and case records. This edition includes several new chapters, among them the use of intratracheal iodised oil in the treatment of obstinate asthma, which the author finds valuable in combination with other measures.

We read in the preface that the primary aetiological factor in migraine is usually food sensitisation. The evidence supplied is hardly convincing. Of the author's cases about one half gave a positive reaction to foods on skin testing, but many foods that gave a definite skin reaction seemed to have no clinical significance in relation to migraine, and other foods whose ingestion was followed by attacks of migraine gave no skin reaction, further a reaction to a suspected food might be negative when tested in one area of the skin and positive in another. One of the five cases recorded was found to be sensitive to twenty-two foods, elimination of which has been followed by freedom for eight months except for two attacks.

This book is written primarily for the general practitioner, but contains a wealth of technical detail which the specialist in allergy will be able to sift to greater advantage.

THE LANCET

LONDON SATURDAY APRIL 3 1937

THE SALE OF NOSTRUMS

LEGISLATORS in the United States are preparing measures for the stricter control of the medicine trade. If they are successful, there will be fresh hope for similar provisions in our own country where a select committee of the House of Commons has lately produced a report¹ on the medicine stamp duties. Although the select committee viewed our problems from the fiscal angle only the report mentions that there was, incidentally authoritative evidence that the poorer and less well-educated classes of our people spend more money than they can afford on remedies of little or no efficacy with an accompanying danger to health as a result of their not seeking medical or surgical treatment in time. These deliberate comments on the obsolescence of the medicine duties and on the exploitation of the public by the appeal to fear merely repeat what has often been officially recorded before. But as the debate on the Medicines and Surgical Appliances (Advertisement) Bill showed a year ago the Parliament at Westminster is liable to discount this kind of advice as a sinister and self interested attempt by registered medical practitioners to deprive poor sufferers of the really valuable advantages of unorthodox medicine.

There are now before the legislature of the State of New York proposals which resemble and improve upon Mr. Duckworth's Bill of last year. The measure proposes to set up a Consumers Bureau in the New York department of health with powers to refuse the registration of any proprietary food or drug and to control the advertising of such articles. The manufacturer will not be allowed registration unless he submits the complete formula of his product if this bureau deems it potentially injurious registration will be refused. This Consumers' Protection Bill as it is named will also prohibit any representation of palliative or therapeutic effect on any of a list of 42 diseases and will curb the extravagant claims displayed on labels or in advertisements of any kind. Meanwhile two other Bills are pending in Congress thus the problem is being attacked both in the federal and in the several States legislatures. It is unwise to dogmatise about American statutes and their prospects. Wide legislative powers were left in the hands of the several States when the historic constitution was framed in the seventeenth century. Limited powers (of which inter state commerce is concerned) were permitted to the federal legisla-

ture. A great part of the time of the supreme court of the United States is devoted to deciding the validity of laws where one legislature is alleged to have trespassed into the domain of another. One of the functions of the federal government is the Post Office federal powers can therefore be used to suppress mail order frauds by "closing the mails" to quack remedies much in the same way as our own Post Office can restrict the postal traffic in Irish Free State sweepstake tickets and literature. In America the National Food and Drugs Act of 1906 requires that the patent medicine package must declare the presence and amount of eleven specified drugs, if the package contains an advertisement of healing powers which is demonstrably false the Government can intervene. Dr. A. J. CRAMP in the introduction to the third volume of his *Nostrums and Quackery* reviewed in our columns a fortnight ago pointed out to his fellow countrymen the shortcomings of the Act of 1906. It deals with advertising only on or in the trade package, not with collateral advertising in newspapers or on hoardings or by wireless publicity. It requires the declaration of only eleven out of thousands of drugs. It confines the word drug to substances used for the cure or alleviation of disease and thus it exempts cosmetics which may often contain dangerous drugs. Dr. CRAMP has hinted that the business slump of 1929 has made the moment less propitious for sterner legislation against quack remedies. In times of prosperity he suggests reputable journals may exercise a rather rigid censorship of medical advertising. When hard times come the standard is lowered. Many newspapers and magazines which helped to educate public opinion and to secure the passing of the 1906 Act are said to have been recently willing to admit advertisements of patent medicines to their columns where once such matter would have been unwelcome. He puts a high estimate on the money spent in advertising campaigns. A maker of patent medicines is quoted as having said that this expenditure amounts to nearly one half of the manufacturer's costs. The United States newspapers are said to derive more profit from the advertisement of quack medicines than the makers themselves from the manufacture. Sentimental statements that patent medicines are the poor man's medicine omit to tell the poor man how large a part of the price of the alleged remedy has been spent in convincing him that he suffers from something which it is sure to cure.

The two Bills now before Congress according to a recent summary in the *Journal of the American Medical Association* propose to regulate the inter state commerce of devices for the diagnosis and cure of disease in man or other animals or devices affecting any function of the body. Both Bills propose to prohibit the advertisement of such persons other than the medical profession of any drug or device represented as having a therapeutic effect upon Bright's disease, cancer, tuberculosis, infantile paralysis, venereal diseases, and heart vascular diseases. If this prohibition is carried

both by the federal and State legislatures of America, it will be no small encouragement to revive the similar proposals to which the Parliament at Westminster refused a second reading last year

CEREBRAL GLIOMAS

WHEN making a diagnosis of cerebral tumour the neuro surgeon endeavours to answer three questions. Is a tumour present? Where is it situated? What is its histological nature? Correct answers may be given to the first two questions in a very high proportion of cases, but the third one is a much more difficult one to answer. In an account of his experiences with 100 cases of glioma of the cerebral hemisphere, Prof L. PUTSEPP discusses¹ these aspects of diagnosis. He divides his cases into three categories, according to their clinical evolution, and each group is correlated with the operative findings. In 45 cases the symptoms and signs developed in a slow and progressive manner, which is considered to indicate a benign lesion, in 32 of these the tumour was an astrocytoma. The next group (number unstated) includes those in which the symptoms developed in paroxysms, with periods of amelioration. In three-quarters of these a cystic tumour was found at operation. Prof PUTSEPP believes that aggravation of symptoms is due to hæmorrhagic infarction of the tumour, and recession follows cystic degeneration of this area. Some authorities are more inclined to associate cyst formation with an exacerbation of symptoms. Group three consists of cases with an "acute" history, in these the tumour was soft and ill defined, typical of spongioblastoma multiforme. Oligodendroglioma is also placed in this category. This tumour has long been regarded as benign and of slow growth, tending to calcify, but from a study of its natural history it is clear that eventually it may acquire malignant characteristics, and in some areas its histological picture may be very like that of a spongioblastoma multiforme.

To distinguish between glioma and meningioma the following investigation has been found valuable. If the patient with a suspected glioma is given an intravenous injection of hypertonic saline the general symptoms (headache and vomiting) are likely to improve, but the focal signs to persist or even to be aggravated if the diagnosis is right. If the tumour is actually a meningioma focal signs as well as general symptoms will show improvement. Prof PUTSEPP avoids the partial removal of a glioma, believing that this procedure leads to activation of the remaining portion of the growth. If by reason of its location the tumour cannot be entirely removed, he employs a two stage "physiological" method. At the first session the brain is incised until the tumour is exposed, the bone of the osteoplastic flap is removed, and the wound closed. Two or three weeks later when the flap is again reflected, the tumour will be found to have migrated nearer the surface of the brain. Total ablation of the tumour can then be effected with

minimal sacrifice of healthy brain. The bone of the flap is also removed as a routine measure when the tumour is "soft"—i.e., spongioblastoma multiforme, for this provides ample decompression in the event of a recurrence of the tumour. When a cystic tumour has been dealt with, a small portion of the overlying bone is removed so as to form a window. Any further collection of fluid can easily be aspirated through this opening. For those cases in which the tumour cannot be removed, decompression is obtained by performing an extensive craniectomy immediately over the tumour. The classical subtemporal decompression is never utilised, for in PUTSEPP'S view the other procedure gives a much better result. Various arguments are offered in support of "focal" decompression, and these are considered to outweigh very considerably the disadvantage of disfigurement.

It is unfortunate that though many figures are given in this article they are difficult to follow, being set out partly in actual numbers and partly in percentages. This is especially disappointing where late results are under discussion. For example, of the 28 cases of astrocytoma 3 are still alive 10–12 years after operation, and apparently 8 survived 4–6 years. These figures compare favourably with those given by CAIRNS in his recent survey of the ultimate results of operations for intra cranial tumours. The vast majority (86 per cent) of patients operated on by Prof PUTSEPP for spongioblastoma multiforme died within a year of operation. Some of the patients with this type of tumour were decompressed and the tumour treated by deep X radiation. These showed a very slight gain in longevity as compared with those in which a radical removal of the tumour was attempted. The opinion is given that the functional results also were slightly better in those cases treated by radiation.

INHERITANCE OF RESISTANCE TO INFECTION

IN recent years much work has been done, especially in America, on the problem of the inheritance of resistance or susceptibility of laboratory animals to different bacterial and virus infections. The accumulated data were summarised and reviewed in 1934 by A. BRADFORD HILL in a report to the Medical Research Council.¹ HILL concluded that between strains of the same species differences in mortality from specific infections had been shown to exist, which could be ascribed to differences in genetic composition, that within strains selective breeding had given results which, in some respects, lacked uniformity and made interpretation difficult, but in general led to the conclusion that resistant and susceptible lines could be developed, and that the factors for resistance were dominant to those for susceptibility. How far these factors were specific, giving immunity to only one infection or to similar types of infection, how far they might extend their influence over a

¹ *Bruz. méd.* Jan 31st, 1937, p. 491

¹ *Spec. Rep. Ser. med. Res. Coun. Lond.* No. 196

wide range of dissimilar harmful agents was a problem to which the available evidence gave no conclusive answer

One of the most assiduous workers in this field has been LESLIE T WEBSTER of the Rockefeller Institute for Medical Research. In his earlier work and in that of other investigators the development of resistant stock was based upon breeding from survivors to infection. An objection to that procedure has been raised—namely that the progeny may prove more resistant to the infection because of their selection through mortality resulting through infection conveyed by the previously infected parents or by a transfer similarly conveyed of an active or passive immunity. Elaborate tests have been made which show that such factors are not likely to be the whole explanation of the enhanced resistance of the progeny but the probability remains as WEBSTER himself admits, that the persistent infection is a factor in raising the resistance of the tested offspring. In his later work WEBSTER has carefully avoided this difficulty by breeding again from uninfected parental stock whose first litters have been proved to be very resistant or susceptible to various infections. By this means he has developed lines of mice which differ widely in their reactions to different agents. In a paper recently published² he gives an account of the position which has been reached in this way and also full details of later tests with a variety of bacterial and virus infections. By rigid selection testing and discarding procedures on over 13 000 mice for 12 generations from 1930 to 1934 three main inbred lines reacting with reasonable uniformity have been produced. The first of these is very susceptible to infection with *B. enteritidis* and practically all mice of the latest generations succumb to the test dose with this organism; they are also susceptible to an induced virus infection (encephalitis St. Louis type is employed) and 80-90 per cent die at test. They are termed bacteria-susceptible virus-susceptible. The second line appears to be equally susceptible to the bacterial infection but are resistant to the virus for less than 10 per cent succumb to the test with it; they are termed bacteria-susceptible virus-resistant. The third line shows considerable resistance to *B. enteritidis* 17 per cent dying at test but nearly all succumb at the test with virus; they are termed bacteria-resistant-virus-susceptible. A fourth line resistant to both bacterium and virus is at present being developed.

The first three lines have given sufficiently stable mortality rates for it to appear likely that cross breeding and back-cross experiments would allow the mechanism of inheritance to be analysed and the results of such tests are now reported. They support the conclusion previously reached that with the infecting agents used resistance is dominant over susceptibility; the factors do not appear to be sex-linked and those regulating resistance to *B. enteritidis* are not related to those regulating resistance to encephalitis virus. Finally

the tests indicate that the mechanism of this inheritance may be relatively simple for the mortality rates of the F_1 , F_2 and back-cross mice approximate roughly to those expected on the basis of two single factor crossings. It seems however that the type of general title given to the lines—e.g. bacteria-susceptible virus-resistant—may be somewhat misleading. All the lines appeared equally (and highly) susceptible to a strain of mouse passage rabies virus so that the factors involved may be more narrowly specific than the titles suggest. The nearest approach to a solid immunity is a virus-resistant strain of which only 18 out of 209 died at test.

The work here reported has clearly and inevitably been laborious for large numbers of mice of each generation in each line and the cross breeding experiments must be bred for valid conclusions. Also complications creep in environmental influences are difficult to control and changes in mortality rates sometimes take place which cannot be readily explained and are attributed to unknown environmental causes. WEBSTER has done much to overcome these difficulties; his present paper is an addition to the subject matter that well deserves careful study.

MORPHIA AND BILIARY COLIC

It is astonishing how little we still understand about that commonest of symptoms pain. An investigation that succeeds in defining any single type of pain and displaying its mechanism is therefore always welcome and valuable. BURSON, MCGOWAN, and WALTERS, of the Mayo Clinic^{1,2} have by very simple methods thrown light on a variety of pain which may arise in the biliary tract after cholecystectomy and which naturally brings disappointment to both patient and surgeon. A T tube left in the common bile-duct for post-operative drainage was connected by means of rubber tubes and a Y junction to a manometer and a reservoir and the system filled with saline. When the reservoir was raised the manometer recorded the pressure existing in the biliary tract and in one case a clear association could be demonstrated between rise of pressure and attacks of pain in the upper abdomen extending round the costal margin and to the abdominal blade. A means of relieving this pain was found namely morphia. This was shown by tests in 1914 to increase the ease of the pain. Oddi. In fourteen experiments the administration of a grain of morphia caused a pressure fall in 2-3 minutes and reached a plateau of 20 to 25 mm. in 10 to 15 minutes. During the fall and fall 2 minutes generally then it rose slowly away as the patient's condition improved on the coast. The next pressure lowering dose was given 15 to 20 minutes later.

communicate with the rest of the system it could be raised by hand until a head of pressure was attained, sufficient to force the sphincter of Oddi, when saline flowed through the tubes and into the duodenum. The head of pressure required was a measure of the tightness of sphincteric contraction, and the method showed it to be much higher after morphia than before it. Confirmation of this finding was obtained by injecting radio opaque oil into the common bile duct, and photographing it. Before morphia was given, the oil would fill the common duct and pass in considerable amount into the duodenum, after morphia, however, the injection would force oil up into the hepatic ducts, which with their tributaries appeared clearly outlined on the films while the duodenum remained almost or quite empty.

Codeine and Dilaudid, like morphia, produced a spasm of the sphincter of the common bile-duct.

The experiments are few but their results are so striking that they should make us think twice about giving opium alkaloids to patients with post cholecystectomy colic. Then what shall we give? The authors have further tracings showing a sharp and satisfactory fall in the pressure inside the bile duct as soon as amyl nitrite is inhaled, or shortly after glyceryl trinitrate is placed under the tongue. These were much more effective in relaxing the contracted sphincter than many other drugs tried, and they also brought relief of pain. This piece of work is a neat example of how the physiologically minded surgeon can turn to good account the opportunities that surgical operations afford.

ANNOTATIONS

THE SIGNIFICANCE OF ANTIFIBRINOLYSIS

Tillett and Garner's observations on the fibrinolytic activity of streptococci, and on the development of resistance to this action, opened a new field in the study of streptococcal infection. They themselves showed that plasma clots from patients convalescent from known infections by *Streptococcus pyogenes* were highly resistant to lysis by cultures of this organism, and it was not long before others extended this method of study to conditions of more doubtful nature. Hadfield, Magee, and Perry¹ were the first to show that resistance to fibrinolysis was developed during the course of rheumatic fever, an observation which has since been confirmed by others, and now forms part of a serological argument fundamental to the conception that rheumatic fever is an allergic reaction to streptococcal products. Some observations now published by Waaler² are interpreted as questioning the validity of this conclusion, on the ground that the development of antifibrinolysin appears not to be a strictly specific reaction. This study embraced in the first place 31 cases of apparently infective polyarthritis of various types, and in half of these resistance to fibrinolysis was developed and varied in degree with the activity of the disease, as has been observed in rheumatic fever itself, an exception was afforded by 5 cases of Still's disease, all of which gave negative reactions. In this there is nothing inexplicable or inconsistent with existing belief since other antibodies to *S. pyogenes* have been found in the serum of patients suffering from multiple arthritis. But Waaler has also found increased resistance to fibrinolysis in patients suffering from bacterial endocarditis demonstrably due to streptococci of other types, four being *S. viridans* and one *S. faecalis* and in two patients with the most pronounced reactions there was not even a history of rheumatic fever. He concludes from this that the reaction is non specific and must not be accepted as evidence of infection by *S. pyogenes*. This conclusion is open to criticism on two grounds. One concerns the reaction itself: the question here is the interpretation to be placed on a certain degree of resistance, and those who have worked with this test have found it difficult so to standardise conditions as to place reliance on much more than a simple positive or negative result. The other concerns the

nature of his five cases of bacterial endocarditis. In spite even of a negative history, the probability is that they had their origin in a rheumatic endocarditis, and since it has been found by Von Glahn and Pappenheimer³ that active rheumatic lesions in the form both of bacteria free vegetations and of Aschoff nodules in the myocardium may still exist at the time of death from bacterial endocarditis, it cannot be assumed that the rheumatic process is in these cases simply a thing of the past.

THE OLD ASHMOLEAN MUSEUM

AMONG the various good causes in Oxford which may get help from the appeal which the university has lately made we hope sympathetic consideration will be given to the Old Ashmolean or, as it is now called, with a sad loss of elegance as well as historical interest, the Museum of the History of Science. The building, inside and out, is one of the loveliest in Oxford, built by an unknown architect at the end of the seventeenth century to house the miscellaneous collections of Elias Ashmole and the Tradescants. Part of the building housed the first chemical laboratory, and was the meeting place of the early scientists. It was in one way and another neglected and deteriorated, some of the exhibits disappeared, and the proctors ordered a mouldering dodo to be burned, though happily its head and legs survived. But in the last 20 years there has been a renaissance. Dr Lewis Evans gave his unrivalled collection of mathematical instruments, and Mr R. T. Gunther, LL.D., entered on his enthusiastic curatorship which ordered what was there and found much else of great interest and historical importance in the cellars and attics of various colleges, once the museum took life again, gifts and loans came in abundance. As our readers will remember Dr Gunther has also published a series of volumes on the early history of science in Oxford. As has always happened, science and medicine were in the early days more intimately associated than they are now, and there is a great deal of medical interest in the museum—old pharmacists' cabinets with the drugs waiting to be critically examined, microscopes, a Valentine's knife, phlebotomist's gear, perflatory spoons for administering cod liver oil, and much else that appeals both to the curious and to the serious student. The present trouble is that Dr Gunther's curatorship has been

¹ Hadfield, G. Magee, V. and Perry, C. B. (1934) *Lancet* 1 834.
² Waaler, F. *J. clin. Invest.* January 1937 p. 14.

so successful that the museum has hopelessly outgrown its accommodation which is limited to the topmost of the three floors of the building of which it needs the whole. The bottom and middle floors are occupied by the Bodleian Library and by the lexicographers who are engaged on a new edition of Lewis and Short. If these can be moved elsewhere which should not be difficult the Old Ashmolean will at comparatively small cost be able to blossom out into what it is quite ready to be—one of the most attractive institutions in the university.

HISTAMINE AND RENAL LESIONS FOLLOWING SHOCK

SINCE the circulatory depression resulting from injection of histamine is likely to diminish the secretion of urine Bjerring¹ has investigated the fall of blood pressure and the reduction of the urea and creatinine clearance that follow injection of histamine. He finds that the reduction of the renal function is not always proportional to the fall in blood pressure, and he concludes that histamine must have some direct action on the renal blood vessels. It is to be noted however that the experiments were done on patients suffering from various diseases that might modify the findings. In a further paper Husfeldt and Bjerring² describe two cases of patients dying in uræmia eight days after receiving severe injuries. Post-mortem section of the kidneys showed absence of blood from the glomerular tufts and some degeneration of the tubules. On the histological appearances the authors dispose of trauma to the kidneys or incompatible blood transfusion as causes of this lesion and they suggest that it is due directly to defective renal circulation during shock. They mention that histamine may cause albuminuria as well as deficient function. Adrenaline and Ephedrin (synthetic ephedrine) may also produce albuminuria and it is interesting to note that signs of renal damage did not develop fully until three days after the injury with a rising blood pressure indicating vasoconstriction.

PAY BEDS IN LONDON VOLUNTARY HOSPITALS

THERE are many people able and willing when they are ill to pay the cost of maintenance in a hospital as well as a reasonable fee for medical attendance but who cannot afford the usual charges of a nursing home. In many of the London voluntary hospitals beds are now available either in cubicles, single rooms or small wards for persons of moderate means. The number of such pay beds has increased from 590 in 1920 to 2112 last year and details are given in the new edition of a list³ issued by King Edward's Hospital Fund for London. Medical and surgical fees are not as a rule included in the weekly charge: they are arranged between patient and consultant, or more commonly through the family doctor. The normal weekly charge as given in the list does not include anaesthetist extra nursing exceptionally expensive drugs or dressings treatment by electricity or light, radium or X rays, pathological examinations or operating theatre expenses. The list calls attention to the two contributory schemes which facilitate for all parties the use of these pay beds. For persons with incomes not exceeding £5 a week (for a married man with children under 16) there is the Hospital Saving Association for persons whose incomes exceed this limit there

is the British Provident Association. A number of societies approved under the national health insurance scheme also provide hospital treatment for their members. It is difficult to state precisely how many approved societies do so for quite a number of them exclude women from hospital benefit and others only pay in respect of members who were in the society during a more spacious time when money for this purpose was accumulating. A useful list of these societies and of the limitation in the benefit provided has just been issued⁴ by the Central Bureau of Hospital Information.

FREEZING AND THAWING THE TISSUES

WE are familiar in this country with the work of Sir Thomas Lewis on the reaction of the tissues to local injuries and with Sir William Bayliss's humoral theory of secondary shock. The former demonstrates the liberation of a histamine like substance at the site of injury and the latter postulated the dissemination of a chemical substance from areas of massive injury causing a general loss of plasma from blood vessels to tissues. A similar condition was brought about by histamine and "histamine shock" and secondary surgical shock were thought to be identical. Nowadays this interpretation of secondary shock has been practically discarded with the reservation that it may account for some features of the condition. A view which is gaining ground, chiefly due to work from America is that the loss of fluid from the circulation can be sufficiently accounted for by exudation into the injured tissues themselves. The original experiment of Cannon and Bayliss⁵ who occluded the circulation to an injured limb and stated that shock was absent until the circulation was released has not, it is said been satisfactorily repeated. This is curious for if the modern theory is correct loss of fluid from the blood stream into the injured tissues could not take place unless these were included in the circulation and if they were temporarily excluded it would be reasonable to expect shock to occur on restoration of the blood flow.

There seems no doubt, however that extensive local injury can abstract sufficient fluid to concentrate the blood as much as 50 per cent and lower the blood pressure to about 80 mm Hg in experimental animals. This has been confirmed by H. V. Harkins and P. H. Harmon⁶ of Chicago for injury by freezing in anaesthetized dogs and they say that the exudate resembles blood plasma very closely in composition. They also point out that although this brings freezing into line with burning and mechanical injury the exposure to extreme cold of sufficient of the body to produce shock in the human would bring about death from other causes.

Their communication is interesting from a more immediately practical point of view in that it casts doubt on the traditional conservative treatment of frozen tissues. The evidence they have collected up to the present suggests that rapid thawing is no less effective and no more harmful than slow thawing. Their criterion is the extent of gangrene and so forth in narcotised animals but in ordinary therapeutics the factor of pain would have to be taken into account and might well be decisive in determining which treatment to adopt. This again brings us back to the question of shock. It has been shown in Cannon's laboratory that repeated injections of adrenaline will ultimately cause a fall of blood pressure and increased blood concentration. This is supposed to

be a result of continued peripheral vasoconstriction with consequent asphyxia and increased permeability of the capillary walls. Yet another theory of shock emerges from this work to account for those cases in which trauma is absent, though if established it would apply equally to traumatic cases. It is postulated that a sudden intense stimulation, such as an explosion, might overstimulate the sympathetic-adrenal system and bring about the same results as persistent administration of adrenaline. The possibility of a general effect in severe local injury is therefore reintroduced, and it seems that the final picture of secondary shock might closely resemble the condition described by Bayliss, although he was at fault in the interpretation of his experiments and regarded nervous effects as having been excluded.

ANTECEDENTS OF PYORRHOEA

At a meeting of the odontological section of the Royal Society of Medicine on March 19th, to which the Birmingham Odontological Society had been invited, Dr Wilfred Fish reviewed the local and general effects of oral sepsis in the light of Okell and Elliott's observation that tooth extraction may cause transient bacteraemia, and the further conclusion, by Maclean and himself, that streptococci and other organisms in pyorrhoea are normally confined to the periodontal sulcus and do not actually invade the tissues.¹ Thus situated, he believes, such organisms may produce disease by the diffusion of toxic products into the local tissues or by the further dissemination of soluble toxic matter into the system generally. Alternatively both local and general diseases may follow the actual traumatic introduction of the organisms themselves into the blood stream by extraction of the tooth, or even by chewing hard food.¹ This bacteraemia associated with tooth extraction or with mastication is likely to be harmless unless the organisms are arrested somewhere in circumstances favourable to their growth. They may, for example, be entrapped in a vessel of the alveolar bone by bruising with the forceps during extraction, or a slight blow on a bone, such as the tibia, at a moment when organisms happen to be circulating in the vessels concerned might also imprison the germs and leave them to multiply and produce osteomyelitis, or, again, as Okell and Elliott pointed out, they may attack the fibrous vegetations of a simple endocarditis. To prevent this last catastrophe, Dr Fish holds that no dead tooth should be extracted from a patient with endocarditis and even a live tooth should be removed only when there is urgent necessity, and only after careful crutisation of the periodontal sulcus. He recommended that patients with simple endocarditis and also much chronic gingivitis should keep to soft food. They must not brush or rub the teeth and gums, since this also causes a bacteraemia, and the only permissible treatment is to dress the gum margins very gently with a paste of zinc oxide and oil of cloves which is carried on wisps of cotton wool into the periodontal sulci and left there for several days. This eliminates pus from the pocket. The local effect of toxic absorption from the pocket is eventually 'pyorrhoea'—a breakdown of bone and fibrous tissue which deepens the pocket and loosens the tooth. But Dr Fish was at pains to explain that it is by no means necessary to extract the teeth in order to prevent both the toxic absorption and bacteraemia since the organisms are living on the surface in the periodontal sulcus. Pyorrhoea, he

maintains, can be cured by cutting away the pockets in which the organisms grow and afterwards rubbing the surfaces of the gum to harden and hornify them, thereby preventing toxic absorption. "In this way the patient keeps his teeth, gets a clean mouth instead of a dirty one and is safe from the remote effects of oral sepsis." It is useless on the other hand to extract a few dead teeth or teeth hopelessly loosened with pyorrhoea and leave infected gum margins round the rest. Every gum margin histologically examined by Dr Fish has shown some degree of chronic inflammation, and every patient suffering from toxic absorption should in his opinion have a careful toilet of the gum carried out on the remaining teeth in addition to the extraction of any that are hopeless. Only thus can accurate clinical conclusions be drawn concerning the effects of oral sepsis on the general health.

IN MEMORY OF ALFRED KEOGH

THE Army Council have decided to name the new barracks in the course of construction for the R.A.M.C. Depot and Army School of Hygiene at Aldershot the "Keogh Barracks" in memory of Sir Alfred Keogh, who was Director General, A.M.S., from 1905 to 1910 and again during the late war from 1914 to 1918. That Keogh's memory should be kept alive by the Army Council, and indeed by us all, is right. No one man ever did so much for the Service which he ornamented, and to which during the war the country owed so great a debt. He was the first to see that wherever connexions could be established between the civilian and military doctor, the advantage would be great and direct. During his first term as D.G.M.S. he visualised how civilian medicine could be made to coöperate with the R.A.M.C., not only in times of peace but in times of emergency; and when those times arrived with a world war a comprehensive plan was already in existence to meet the enormous difficulties of the medical department of the Army. Without Keogh's prevision vast tragedies might have occurred. He had looked forward with an uncanny anticipation, so that he was able to gather round him from the beginning of the struggle a fine personnel organised from civilian doctors and representative consultants, and to find material for special war hospitals. The foundation of the R.A.M.C. College represents only a part of what the Service owes to Keogh. His large performance was to utilise the medical knowledge of the country with intelligence and economy during a period of tremendous strain, if similar strain occurs again, this country knows, mainly thanks to Keogh, how it can best be met.

"EPILEPSIA"

THE case for international coöperation is nowhere stronger than in the field of medical research. In various ways, and in different countries, the problem of epilepsy, for instance, is being attacked by individual neurologists, psychiatrists, biochemists, and social workers, but want of knowledge of the activities of others and lack of any coördination has hampered progress and rendered valueless many good pieces of individual work. For four years before the late war an international league existed to promote coöperation among medical men who were interested in epilepsy and to broadcast information about what different countries were doing. After twenty years of inactivity this league has now been resuscitated and we have received the first number of its new journal *Epilepsia*, which will be published in future, at least once a year, under the editorship

¹ See *Lancet* Jan 2nd 1937 p 31

of Dr H I Schou of Denmark.¹ The journal is printed in English and the story it tells is a hopeful one. The League has made a good start with a membership of about 260 and already there are flourishing branches in America Scandinavia and Great Britain with promise of more to be added shortly. The first number of the journal is necessarily introductory in character. The outstanding feature is an able survey of the problem of epilepsy and the means of attacking it by Dr W G Lennox of Boston the president of the League. Dr L J J Muskens of Amsterdam discusses the ideal facilities for the treatment of epilepsy emphasizing the need for special hospitals at which all incipient cases should receive thorough investigation. Some account is given of the facilities for the residential treatment of epileptics that now exist in different countries and many of us will find useful the detailed and complete list of institutions for epileptics in Great Britain. It is hoped that future numbers of the journal will contain a résumé of research work carried on in different countries. We are glad to know that the British branch with over a hundred members has already had a successful meeting and we understand that the secretary of this branch Dr Macdonald Critchley (137 Harley street, London W1) hopes to hear from other medical men who are interested.

AFRICAN HORSE-SICKNESS

For nearly 50 years veterinarians in South Africa have been striving to combat horse-sickness a disease first described by some of the early explorers of the African Continent which has made it almost impossible to use susceptible horses and mules throughout vast tracts of country. The late Sir Arnold Theiler and his colleagues at the Institute of Veterinary Education and Research of the Union of South Africa Onderstepoort identified the causal agent as a filtrable virus many years ago and directed their attention to devising methods of protecting equines from infection. Apart from the testing of empirical prophylactic and therapeutic procedures advocated by farmers and others from time to time two lines of research have been followed, the one being to identify the method of spread of the disease and the other to produce a satisfactory active immunity. All epidemiological evidence indicates that infection is transmitted by a night-flying insect vector such as the mosquito. Apart therefore from testing the protective value of measures designed to ward off such insects extensive attempts have been made to identify the species of insect responsible. In their reports of the investigation O Nieschulz A H Bedford and W O Neitz² describe the feeding on infected horses of 4500 clean mosquitoes belonging to the genus *Aedes* and their failure to transmit the disease when subsequently allowed to feed upon susceptible animals. Various other genera besides *Aedes* are possible vectors and the identification of the vector might well become a tedious process of elimination. Fortunately owing to recent improvements in methods of immunisation indicated below the identification of the vector has become a problem of academic rather than practical interest. Attention has also been centred on the natural reservoir of infection. Horses are known to harbour virus for many months after recovery but the presence of

such virus is difficult to demonstrate. Since horse-sickness has appeared among susceptible horses introduced into districts where no equines were previously to be found it seems unlikely that equines constitute the only important natural reservoir. Dogs can be artificially infected but there is no evidence that this circumstance has any epidemiological importance.

As to immunisation until recently equines had to be used for investigations which were thus cumbersome and expensive nevertheless research proceeded steadily and a significant advance was made by the discovery of a strain of virus of low pathogenicity but reasonably good immunising capacity. Using this strain a method of immunisation was developed of administering a double inoculation consisting of an intravenous inoculation of mild virus followed six days later by a combined intravenous inoculation of virulent virus and nearly half a litre of immune serum. For many years this form of inoculation was practised in many parts of Africa with reasonable success. According to du Toit (1934) 2-3 per cent of horses died from horse-sickness as a direct result of the immunisation 3-4 per cent died as a result of breakdown of immunity and 0.1 per cent died of acute liver atrophy (staggers) following immunisation. These figures apply to police horses kept under good conditions amongst farm animals losses were higher and in view of the high cost of the immune serum and the large dosage required the occasional breakdown of immunity and the inexplicable though rare occurrence of acute liver atrophy this method though useful was clearly far from ideal. Formalised virus was then tried but three injections were required in horses followed by a dose of virulent virus to secure a strong and lasting immunity and such a procedure was clearly unsuitable for routine use.

At this stage the reports of American workers on yellow fever presented a new method of attack. M. Theiler (1930) reported the infection of white mice with yellow fever virus by means of intracerebral inoculation the virus becoming neurotropic during the course of brain passage. Later Sawyer Kitchen and Lloyd (1932) reported that such neurotropic virus had low lethal and high immunising capacity. O Nieschulz (1932) and R A Alexander (1933) discovered independently that mice could be infected with horse-sickness by intracerebral inoculation the virus becoming neurotropic during passage. Nieschulz failed to demonstrate sufficient attenuation of the virus for immunisation purposes but Alexander working at Onderstepoort found that after about 100 mouse-brain passages neurotropic virus could safely be injected subcutaneously into horses and that animals so injected developed a strong immunity to pantropic virus. In developing the neurotropic virus for immunisation purposes the existence of antigenically distinct virus strains had to be considered. Working with three different neurotropic strains Alexander (1936)³ found that horses inoculated with a mixture of three strains showed as a result a strong immunity to all three. It would appear therefore that no antagonism exists between virus strains. Whether a polyvalent vaccine is really necessary or not can only be proved by extensive field trials. The most recent report by Alexander Neitz and du Toit (1936)⁴ records the immunisation of equines with neurotropic virus in a large field experiment in which a reasonable estimate of the value of the new technique could be made. A trivalent vaccine

was prepared by mixing filtrates of emulsion of brains of mice infected with three important virus strains. The preparation of such a vaccine is complicated by the fact that the incubation period of the virus in mice differs for each strain, the authors claim, however, that the procedure was quickly reduced to a simple and inexpensive routine. The vaccine was issued as 10 c.c. doses for subcutaneous inoculation, and it was found that about 600 standardised doses could be prepared from 48 mouse brains. During the period 1934-35 1815 police horses were immunised by single inoculations of the new vaccine. There was no mortality as direct result of the inoculation and no adverse after effects were reported except for a breakdown of immunity in 0.66 per cent of animals when exposed to natural infection. Among 28,659 other horses and mules from various sources, 3 deaths were reported which may have been due to vaccination and the immunity broke down in 0.87 per cent of animals. So much is known of the usual incidence of horse sickness when no immunisation has been carried out that the value of the vaccine would appear to have been demonstrated, in spite of the absence of controls in this particular experiment. Incidental points remain to be investigated for instance, possible after effects of neurotropic vaccination upon fecundity or pregnancy, the possible formation of irreparable lesions in the central nervous system followed by paralysis, the duration of immunity and the length of time vaccinated animals remain reservoirs of infection. These considerations are of minor importance, the new neurotropic vaccine stands out as a highly satisfactory outcome of many years of patient and unremitting research.

A DEMAND FOR ACTION

"To inquire into the diet of the people, and to report as to any changes therein which appear desirable."

SUCH is the task of the Advisory Committee on Nutrition appointed by the Minister of Health and the Secretary for Scotland, and in presenting their first report they claim that "this is the first occasion in history that a comprehensive survey, statistical and physiological, of the diet of a whole nation has been set on foot by any Government." The report is a preliminary description of the situation as it is to day, with suggestions about the changes immediately needed. The Committee range themselves clearly on the side of those who preach the advantage to be gained from an adequate supply of the right kinds of food. "We believe," they say, "that better physique and health can be obtained and resistance to disease increased by the application to human diets of recent knowledge which demonstrates the importance of certain classes of food for proper nutrition." They admit that the facts lately brought to light are too complex for the layman to grasp, but they consider that the practical lesson to be learnt from these facts is very simple indeed. It is merely that we must include in the dietary of the whole community—and especially of mothers and children

—enough of the "protective foods." The term "protective," originally given by McCollum to milk and green vegetables, is now applied generally to all foods rich in the nutrients that research has shown to be essential for health—especially milk and milk products, green vegetables, fruit, and eggs. The consumption per head of most foodstuffs has increased in this country since before the late war, the largest increases being in condensed milk, fruit, butter, vegetables (other than potatoes), eggs, tea, margarine, and cheese. Indeed, the consumption of butter and margarine together is now, per head, 56 per cent higher than it was in 1909-13. On the other hand the quantity of cereals used has fallen by nearly 10 per cent and of fresh milk and cream by 6 per cent. Examining the national food-supply as a whole the Committee find no aggregate deficiency of calories, fats, or proteins, but they hold it probable that there are deficiencies, of fat and of animal protein at least, among the very poor. They underline Sir John Orr's conclusion that the consumption of the best foods—fresh milk, butter, meat, fish, eggs, fruit, and vegetables (other than potatoes)—rises progressively with income, whereas that of flour and potatoes remains nearly constant, while the amount of margarine and condensed milk used goes down, and in order to secure more complete data they propose further investigation of income distribution, family budgets, and domestic wastage. They believe that the national consumption of fruit and vegetables is too low, especially among the poor, but what they chiefly regret is that the present national consumption of liquid milk is less than half their optimum of seven eighths of a pint per head per day. Children, they say, should have 1-2 pints, expectant or nursing mothers about 2 pints, and the rest of us half a pint; and without going into the economics or politics of milk they "deplore the fact that, while the volume of milk offered for sale is growing and there is a substantial surplus which it is beyond the capacity of the liquid milk market to absorb, there should be at the same time a severe deficiency of milk in the diet of large sections of the population. That under-consumption of a foodstuff so important as milk should exist in a country so eminently suited for milk production, is a matter towards which we cannot remain indifferent." They hope that in dealing with this problem the primary objective of the State will be to ensure that a sufficient supply of safe milk is brought within the purchasing power of the poorest—a measure which in their opinion would do more than any other to improve the health, development, and resistance to disease of the rising generation. The steps already taken towards this end, such as the milk in schools scheme, are a good beginning, but as the Committee rightly say, they do not provide enough milk for all mothers and children who need it, while very little provision is made for adolescents. It is encouraging to find that the report has already borne first fruit in a circular addressed to local authorities by the Ministry of Health, urging them to review their present arrangements in the light of the recommendations now so strongly made.

* Minister of Health. First Report of Advisory Committee on Nutrition. London. H.M. Stationery Office. 1937. Pp. 52. 1s. The members of the Committee are: Lord Luke (chairman), Mrs. Eleanor Barton, Mr. J. N. Beckett, Dr. G. F. Buchanan, Prof. F. P. Cathcart, M.D., F.R.S., Mr. R. R. Enfield, Dr. J. All on Clover, Dr. J. M. Hamill, Mr. A. Bradford Hill, D.Sc., Sir Cowland Hopkins, F.R.C.P., F.R.S., Dr. Donald Hunter, Mr. F. M. H. Lloyd, Dr. E. Mellanby, F.R.S., Sir John Orr, M.D., F.R.S., Mr. L. C. Ramsbottom, Mr. J. M. Vailant, M.D., Mr. Ruth Preuss, Mr. E. C. Ramsbottom, Mr. J. H. T. Wiltshire, Dr. T. W. Wade, Mr. J. R. Willis, and Mr. F. H. T. Wiltshire, with Mr. W. J. Peete and Mr. N. F. McNeill as secretaries and Dr. H. E. Mudge as medical secretary. The late Mrs. Chalmers Watson, M.D., was also a member.

MODEL TRAFFIC LIGHTS FOR CHILDREN—The Save the Children Fund in conjunction with the Ford Motor Company, Ltd., is issuing an ingenious model which by manipulation shows successively the familiar red, amber and green of the streets, and is intended to teach children how to cross the road in safety. Copies may be had free of charge on application to the fund at 20, Gordon square, London, W.C.1.

PRINCIPLES OF MEDICAL STATISTICS

VIV—FURTHER FALLACIES AND DIFFICULTIES

The Crude Death rate

In using death rates or fatality rates in comparison with one another, or as a measure of the success attending some procedure it must be remembered that such rates are usually affected considerably by the age and sex constitution of the population concerned. The fact that the death rate of Bournemouth in 1935 was 13.3 per 1000 while the rate in Bethnal Green was only 10.3 is no evidence of the salubrity of the latter area. The greater proportion of old persons living in Bournemouth compared with Bethnal Green must lead to a higher death rate in the former since old persons however well housed and fed, die at a faster rate than young persons. The 1931 census shows that there were at that time $2\frac{1}{2}$ times as many persons in Bournemouth as in Bethnal Green at ages over 75 years 70 per cent. more at ages 50-74 and 10 per cent. less at ages 10-40. Any population containing many persons round about the ages of 5 to 20 where the death rate is at its minimum, must have a lower total death rate than that of a population containing many infants or old people at which points of life the death rate is relatively high, even though comparisons at every age show an advantage to the latter. For example the following fictitious figures may be taken

Age-group (years)	District A			District B		
	Population	Deaths	Death rate per 1000	Population	Deaths	Death rate per 1000
0-15	500	2	4	400	1	3
15-30	1000	12	12	800	11	13.75
30-45	2000	18	9	1000	5	5
45-60	1000	10	10	2000	18	9
60-75	300	20	66.67	1000	20	20
75+	100	15	150	400	70	175
All ages	6100	67	11.0	6100	115	18.85

Comparison of the two districts shows that B has at every age-group a lower death rate than A. Yet its death rate at all ages the crude death rate is more than double the rate of A. The fallacy of the crude rates lies in the fact that like is not being compared with like: 72 per cent of B's population is over age 45 and only 28 per cent of A's population; in spite of B's relatively low death rates at these ages over 45 the number of deaths registered must be higher than in A's smaller population and therefore its total death rate must be high.

Comparison of the rates at ages is the most satisfactory procedure for then like is being placed against like, at least in respect of age (so long as the age groups are not too wide in the above example they were made unduly wide for the sake of compression and clarity).

The Standardised Rate

At the same time a legitimate desire is often felt for a single mortality rate summing up the rates at ages and yet enabling satisfactory comparisons to be made between one rate and another. For this purpose the standardised death rate is required. For its calculation (by what is known as the direct method) the mortality rates at ages in the different districts are applied to some common standard population

to discover what would be the total death rate in that standard population if it were exposed first to A's rates and then to B's rates at each age. These total rates are clearly fictitious for they show what would be the mortality in A and B if they had populations which were equivalent in their age-distributions instead of their actual differing populations. But these fictitious rates are comparable with one another and show whether B's rates at ages would lead to a better or worse total rate than A's rates if they had populations of the same age type.

For example if the standard population taken for A and B consisted of 500 persons in each of the age-groups 0-15 and 75 and over 2500 in each of the age groups 15-50 and 60-75 and 3000 in each of the age groups 30-45 and 45-60 then in this standard population A's death rates would lead to a total of 230 deaths and B's rates to 201 deaths giving standardised rates at all ages of 19.6 and 16.8 per 1000. Taking a population of the same age distribution thus shows the more favourable mortality experience of B, and the fallacy of the crude rate is avoided. (The deaths that would occur at each age in the standard population at the death rates at ages in each district are found by simple proportion: they are summed and divided by the total population in the standard to give the standardised rate.)

Clearly these fictitious but comparable rates will be affected by the choice of the standard population. It must be observed however that their absolute level is not of interest: it is the relative position that matters and within limits this relative level is not likely to be materially altered by the use of different standards.

The example taken above is of course a very exaggerated one and such gross differences in population are unlikely to occur in practice. On the other hand the differences that do occur in practice are quite large enough to make the use of crude rates seriously misleading.

For instance the crude death rate in England and Wales, of women from cancer was 103 per 100 000 in 1901-10 and 139 in 1921-30 a very appreciable rise being shown. The corresponding standardised rates were 91 and 99; clearly the larger number of women living in the older age groups (where cancer is more frequent) in 1921-30 compared with the number in 1901-10 is largely responsible for the increase in the crude rates and no more subtle factor need be looked for.

With the present increasing proportion of persons living at later ages (owing to the fall in birth and death rates) it is certain that the crude death rate from all causes in England and Wales will in time begin to rise in spite of the fact that the death rates at each age may continue to decline.

Comparison of death rates may also be affected by the sex proportions of the populations considered for at most ages and from most causes females suffer a lower mortality rate than males. Standardisation therefore is sometimes made both for sex and age. (The methods and the alternative method of indirect standardisation are fully described and illustrated in Woods and Russell's Introduction to Medical Statistics.)

The principles of standardisation are often applicable in experimental work. For instance some form of treatment is applied to certain persons and others are kept as controls. If the two groups are not equal in their age-distribution a comparison of the total result may be misleading. A comparison in each separate age-group must be made or to reach a total figure the two sets of rates at ages can be applied to

some selected standard population. A useful method is to use the treated group as the standard and calculate how many deaths would have taken place in it if it had suffered the same fatality rates at ages as the controls. This expected figure can then be compared with the observed figure.

In considering published crude rates—death, fatality, incidence, &c—one must always put the questions: do the populations on which these rates are based differ in their age or sex distribution, and would such differences materially influence the comparability of the crude rates? Crude rates themselves should never be accepted without careful consideration on those lines.

Statistics of Causes of Death

In making comparisons between death rates from different causes of death at different times or between one country and another, it must be realised that one is dealing with material which is, in Raymond Pearl's words, "fundamentally of a dubious character." The recorded incidence of a particular cause is influenced by such factors as international differences in nomenclature, differences in tabulation, medical fashions in nomenclature, and the frequency with which the diagnosis of cause of death is made by medically qualified persons. One or two simple examples of the risks of comparison may be taken.

MORTALITY FROM CANCER

The crude death rate from cancer in the Irish Free State is well below that registered in England and Wales. Part of this difference may be due to a more favourable age distribution of the population in the Free State—i.e., standardised rates should be used in the comparison—but it is likely that it also arises from differences in the certification of death.

In the Irish Free State considerably more deaths are ascribed to senility than in England and Wales—15 per cent in the former in 1932 against about 4 per cent in the latter. Such a difference cannot inspire confidence in the death rate from such a disease as cancer, in which the majority of deaths fall at advanced ages. In general, in comparing the cancer death rates of different countries or of the different areas of the same country—e.g., rural and urban—it is not sufficient to pay attention to the cancer rubric; other headings such as "uncertified," "senility," and "ill-defined causes" must be taken into consideration, and an attempt made to determine whether transferences between these rubrics are likely to play a part.

The kind of indirect correlation that one may observe is this. It is stated that the cancer death rate is associated with the consumption of sugar, and the level of the former is compared with some measure of the latter in different countries. It is found that the countries with a low consumption of sugar have relatively low cancer death rates. But it is at least possible that those countries which have a high standard of living have a relatively higher sugar consumption and also a higher standard of vital statistics and therefore more accurate cancer death rates, than countries with a low standard of living and less accurate vital statistics. Other "causes" of death—e.g., ill-defined and old age—would need study as well as those attributed directly to cancer.

MATERNAL MORTALITY

It is well recognised that the maternal death rates of different countries are affected by the varying rules of tabulation in vogue. A sample of deaths associated with pregnancy and childbirth that took place in the U.S.A. was assigned by different

statistical offices of the world to puerperal and non puerperal groups according to the rules of those offices (Children's Bureau Publication No. 229). The variability was considerable. In the U.S.A. 93 per cent were tabulated to puerperal causes, in England and Wales 79 per cent, in Denmark 99 per cent. Such differences make international comparisons precarious.

MORTALITY FROM RESPIRATORY CAUSES

In England and Wales bronchitis and pneumonia show pronounced differences in their incidence in different parts of the country at certain ages. It appears that the "bronchitis" of one area may include deaths which would be attributed to pneumonia in another. For instance, the Registrar General concludes that "at both extremes of life London appears to call pneumonia many cases which are elsewhere regarded as bronchitis" (Registrar General's Annual Report, Text, p. 85, 1932). Such "internal" differences are always closely considered by the Registrar General and his reports are invaluable to all who are concerned with the changes in the causes of death.

The Average Age at Death

The average age at death is not often a particularly useful measure. Between one occupational group and another it may be grossly misleading. For instance, as Farr pointed out three quarters of a century ago, the average age at death of bishops is much higher than the corresponding average of curates. But making all the curates bishops will not necessarily save them from an early death. The average age at death in an occupation must, of course, depend in part upon the age of entry to that occupation and the age of exit from it—if exit takes place for other reasons than death. Bishops have a higher age at death than curates because few men become bishops before they have passed middle life, while curates may die at any age from their twenties upwards.

The following misuse of this average is taken from a report on hospital patients.

It is stated that in 31 cases of renal hypertension which came to autopsy the average age of death was 45. "Thus the common fate of the renal hypertensive is to die in the fifth decade of life." This may be a true statement of fact, but it clearly cannot be deduced from the average age: the average might be 45 years without a single individual dying in the fifth decade. The report continues: In 80 cases of essential hypertension which came to autopsy the average age at death was found to be 60, while in 20 cases seen in private practice the average age at death was nearly 70.

"Thus, the fate of the non renal hypertensive is very different from that of the renal. The subject of uncomplicated essential hypertension may reasonably expect to live into the seventh or even the eighth decade."

The first deduction is probably valid though obviously information regarding the variability round those averages is required. The frequency distributions of the age at death for the two groups should be given. The "reasonable expectation" has no real foundation in the figures given. If the subjects of uncomplicated essential hypertension mainly live into the seventh or eighth decade one might reasonably adopt that as an expectation. But if the average age is derived from individual ages at death varying between say 40 and 90, one has no justification for using that average as an expectation.

The author regards statistics as "dull things" and therefore refers to them as "briefly as possible"—so briefly that in his hands they are of very little use.

A difference in the average ages at death from, say, silicosis in two occupations may imply that in one

occupation the exposure to risk is more intense than in the other and thus leads to earlier death but this interpretation can only hold as is pointed out above, so long as the employed enter the two occupations at the same ages and give up their work at the same ages and to the same extent. It is usually very difficult to secure satisfactory evidence on these points, and the average ages at death must be regarded with some caution.

Problems of Inheritance

Literally hundreds of disorders or derangements in mankind have been recorded as showing evidence of hereditary factors. The evidence mainly consists of the appearance of the disease or disability in a more or less orderly fashion among related individuals. In many instances there is no doubt that hereditary factors are important but in others their presence is difficult of proof in the inevitable absence of controlled breeding experiments and the impossibility sometimes of distinguishing genetic from environmental influences. Cases are reported, for example, of a familial incidence of cancer: a man whose father died of cancer of the stomach died himself of cancer in the same site, while his wife died of cancer of the breast and their six children and one grandchild all died of various forms of cancer. This is a very striking family history but it is not necessarily evidence of an inherited

factor. If each of these individuals had been known to have passed through an attack of measles we should not deduce a particular family susceptibility to measles since we know that measles in the whole population is so widespread that a familial incidence is bound to occur very frequently. Similarly we want to know the probability of observing a series of familial cases of cancer merely by chance. Even if that probability is small it must be remembered that the field of observation amongst medical men is enormously wide and a few isolated instances of multiple cases cannot be adequate evidence. Usually too only one part of the field is reported in medical literature for notice is taken of the remarkable instances and no reference made to the cases in which no inheritance is apparent. The data required in such a problem are reasonably large numbers of family histories so that if possible it may be seen whether the distribution of multiple cases differs from the distribution that might be expected by chance or whether the incidence in different generations suggests a Mendelian form of inheritance. Even if the distribution of multiple cases differs from that expected on a chance hypothesis the question of a common family environment cannot be ruled out—e.g. multiple cases of tuberculosis may occur more frequently in families of a low social level not through an inherited diathesis but through undernourishment.

PLANT VIRUSES

AND THEIR RELATION TO THOSE AFFECTING MAN AND ANIMAL*

By REDCLIFFE N. SALAMAN M.D. Camb. F.R.S.

DIRECTOR OF POTATO VIRUS RESEARCH STATION
UNIVERSITY OF CAMBRIDGE

THE first virus disease of any kind to be recognised as such was mosaic in tobacco. It was Mayer of Holland in 1886 who demonstrated both its infectivity by sap inoculations and the absence of any fungi or bacteria in the infective juice. Long before this a protean type of disease producing leaf deformity, dwarfing and reduction of crop in variable degree had been recognised in the potato and referred to as it goes back for over 150 years. The disease which was very widespread in England was regarded as the result of prolonged vegetative reproduction that had induced an incurable senility. The only remedy for this, it was maintained, was to discard the old and create new varieties from true seed obtained by the fertilisation of the female portion of the flower with pollen generally of some other variety. There was in fact a widespread if subconscious sympathy with a plant on whom had been enforced a celibacy which was regarded as unnatural and abhorrent by the agriculturist. That the plant reacted by becoming peevish and degenerate was only what might be expected. The cry of back to nature came from the heart. This view persisted in many quarters in this country even so late as the last war, indeed I may claim some share in helping to dispel the myth which as late as 1912 was firmly held in certain influential quarters.

EARLY WORK

In some years this degenerative disease of the potato was so severe and the resultant crop so had as to threaten the continuance of potato cultivation in this country. In 1778 the Agricultural Society of Manchester invited essays on the cause and possible cure of the trouble. These were printed and some 15 years ago with Prof. W. Brierley's help I was fortunate in discovering a copy and making parts of them known once more. Much interest lies in the fact that the chief diseases complained of seem to have been either a chronic form of crinkle—probably a secondary result of infection with the Y virus—or leaf roll. One competitor felt convinced that the green fly was the cause of all the trouble thus forestalling by about 140 years the discovery made by Oortwijn Botjes in 1920 that the virus disease leaf roll was spread in the field by aphids.

Returning to tobacco mosaic which has ever remained the classic subject for virus research it was Iwanowsky who in 1892 showed that juice from a diseased plant remained infective after passing through a porcelain filter which would hold back bacteria. He further showed that the infective agent multiplied indefinitely within the plant. The virus, he found, was highly resistant to alcohol and to drying and he regarded the disease as due to something either held in solution or carried by minute particles in the cell plasma.

Beljerinek (1890) ignorant of Iwanowsky's work investigated with great thoroughness the disease Mayer had described and reached similar conclusions. He described the infective agent as a contagium fluidum and recognised that such yellows which Erwin Smith in 1888 had shown was communicable by budding or graft was but another example of the same trouble. Löffler and Loesch's discovery that the infectious agent of foot and mouth

Sheffield and Henderson Smith (1931) have studied their formation in the living cell. In an infected cell agglomeration of denser cytoplasm takes place, and the small masses thus formed impinge on one another and eventually coalesce to form a large extra-nuclear vacuolated body. Whether such contain more virus particles than reside elsewhere in the cell is highly probable but not proven. Just as not all plant virus infections are accompanied by inclusions, so not all the cells of an infected plant contain them—in fact, it is only a minority that do so.

Tobacco mosaic—the first virus in animal or plant to be recognised as such—is to day in the very forefront of biochemical and biophysical research. In 1936 Stanley prepared a product showing certain crystalline characters from the juice of tobacco plants infected with mosaic; he claims that it represents the virus agent, and that the crystals are protein auto-catalytic enzymes, which on introduction into suitable hosts bring about the transformation of normal cell constituents to a like body. It will be recognised that this view is identical with that of Bordet's in relation to the multiplication of bacteriophage, and presents similar difficulties. F. C. Bawden has improved on Stanley's technique and found that such crystals were readily obtained from the common as well as from two variant types of tobacco mosaic, and confirmed Stanley in that they are absent from normal tobacco juice. The crystals from the three sources, which were identical in appearance and physical properties, on inoculation to healthy plants reproduced the three original specific types of reaction. The crystals consist of protein and in solution behave as doubly refracting liquid crystals which Bawden and others (1936) have found to be composed of very elongated molecules of enormous size with a molecular weight in the neighbourhood of 10-8 and possessed of distinctive physical properties. Whether these crystals are in fact the virus agent cannot be positively affirmed—that they contain the virus in a highly concentrated form is certain, for dilutions of 10-9 are still active. Nevertheless, Chester (1936) testing Stanley's crystals by Dale's anaphylactic method has shown that they contain an unspecified but quite definite amount of protein that is certainly not virus. Thus and the fact that the crystals account for 80 per cent of the total protein of the plant suggests the possibility that Stanley's isolate may be a crystalline form of protein, itself a product of the reaction of the virus on the healthy plant protoplasm and that the specific virus particles are adsorbed to it. Crystals of this kind have only been obtained from plants infected with the virus of tobacco mosaic, though whether the host is a tobacco or a tomato is immaterial. Efforts to obtain the like from plants infected with the X potato virus, the virus of tobacco necrosis and many others have failed †.

PROPERTIES

The physical properties of plant viruses vary very much, some behave to heat, light, and chemical

† Since the delivery of this lecture much progress has been made along these lines both in America and in this country. Stanley and Wyckoff (Science Feb. 12th 1937) have isolated a protein with crystalline character and very high virus concentration from plants infected with Wingard's tobacco ringspot and similar but non-crystalline heavy proteins from plants infected with the X virus of the potato and cucumber mosaic. Beard and Wyckoff (Science Feb. 19th 1937) have isolated a like body from suspensions of Shope's papillomatosis virus disease of rabbits.

The trend of opinion both in America and in England where important work on the purification and properties of these protein molecules is actively proceeding is to regard them as being the actual virus agent to which the term 'living' as generally understood hardly applies.

reagents in much the same way as do bacteria, but the behaviour of some others—and it is noteworthy that they are those of very small size—is peculiar, thus tobacco mosaic is not inactivated till a temperature of 90° is obtained, whilst if and tobacco necrosis will withstand the action of absolute alcohol for many months. These same viruses can also be desiccated and maintain their full virulence indefinitely. Again, tobacco mosaic crystals are almost immune to proteolytic enzymes, though pepsin eventually destroys the active agent in raw juice, while trypsin is without effect. There are other plant viruses however which are extremely sensitive to heat and chemical reagents or to keeping whether in moist or dry conditions outside the plant, amongst such are to be found three of the most widely spread and infectious viruses—viz, the potato virus Y, tomato wilt, and cucumber mosaic.

Animal viruses are endowed to a high degree with the capacity of inducing in their hosts a variety of antibodies. It is less well known that many plant viruses are equally antigenic. Rabbits inoculated with tobacco mosaic juice or Stanley's crystals, or with the X virus of the potato and several other plant viruses, produce antibodies that are absolutely specific to the virus employed, and its related strains and their presence can be demonstrated as precipitin, complement fixation, or neutralisation reactions. Certain viruses, such as the Y potato virus and the virus of sugar beet mosaic and tobacco necrosis, have failed to call forth any antigenic response in the rabbit. It should be noted that the injection of plant virus juices has not produced the slightest pathological reaction in the rabbit nor has any virus agent yet been found which is pathogenic to both plant and animal.

VARIATIONS

A word must be said about the variations or strains of certain viruses which are found in nature or induced in the laboratory. Multiplicity of strains is much more pronounced in the plant than the animal viruses, thus there are some 70 variations of tobacco mosaic, 40 of cucumber mosaic, and 5 of the X potato virus. If the tendency to vary be regarded as evidence of adaptability, and adaptability as a peculiar function of living matter, then we are confronted with the fact that the virus with one of the smallest particles—viz, tobacco mosaic—varies the most.

A few examples are known where plant viruses have been induced to vary by passage through certain hosts and by treatment such as heat. I have converted a virulent potato X virus into a harmless variety by passage through a sugar beet and a virulent potato Y virus both by passage through a schizanthus and by heat into one of much less virulence.

ANTIGENIC AND PROTECTIVE REACTIONS

In 1933 I described some observations in which it was shown that if a plant were inoculated with the G strain of the X potato virus and some ten days later this was followed up by an inoculation with a severe virulent strain of the same virus, then no reinfection took place and the plant remained to all appearances completely healthy, though of course it still contains the mild protecting strain. The whole phenomenon bears a close resemblance to that of vaccination.

Subsequently I found that Thung in Java in 1931 had shown that a tobacco plant infected with a virulent and crippling form of tobacco mosaic could

not be further infected with a different but rather less virulent form of the same virus. The two observations probably have the same explanation: once a cell is infected with a given virus all affinities as regards that virus are satisfied and no other strain can obtain an attachment. It is a case of first come first served. The protection afforded is rigidly specific. There is no doubt that this type of protection is cellular in nature whereas the animal examples so far reported are humoral.

Recently Findlay and MacCullum (1937) have reported a case of protection in yellow fever which appears to be of the same nature as that described above resting on a cellular basis and not as is general in animals on a humoral one. In plants we have no evidence at all of humoral immunity.

In nature potatoes are often protected against the severe X virus strain by a pre-existing infection with a milder type. Such protection has probably been in force ever since potatoes have been cultivated on a large scale.

The effect of virus infection in plants may be roughly grouped as follows—

- (a) Mottling of the leaves only
- (b) Deformity and crinkling of the leaves, generally accompanied by mottling. The deformity may go as far as the more or less complete suppression of the leaf or its conversion into a thread-like structure
- (c) Necrosis, either as isolated spots or patches on the leaf, destruction of the phloem vessels in the veins, as streaks on the stem or as a dieback from the top of the growing point
- (d) In nearly every case there is a pronounced dwarfing of the plant as a whole which may be so extreme as to make the plant unrecognisable
- (e) The floral organs are frequently imperfect or deformed causing a varying degree of sterility or there may be little or no deformity and yet a considerable measure of sterility

Some characteristic deformities such as the conversion of the leaf lamina to threadlike structures in tomato and the curl and discoloration of the leaf in potato roll simulate genetic mutations or congenital deformity respectively.

These and other facts have given some support to the thesis that a virus agent may be an hereditary gene freed somehow from the chromosome and capable of more or less independent life in the cytoplasm. This theory though attractive is without any experimental backing.

Reaction to Infection

The potato illustrates very clearly two characteristics that are common in virus diseases of plants and are also encountered in virus infections in animals. The first is the carrier the second the disease complex.

THE CARRIER

Every potato plant in the U.S.A. harbours one or more strains of the virus X. In the majority of cases it produces nothing more than a transient faint mottle which disappears as the plant attains maturity: often there is nothing to denote its presence. In a few of our own varieties such as Epicure and Arran Crest the same virus is lethal in its effect. Many years ago my colleague Le Pelley and myself found (1930) that every King Edward plant that exists contains a virus which when communicated by grafting to such varieties as Arran Victory or Arran Chief produced a crippling and incurable disease which we called paracrinkle: yet the King Edward plant itself shows not the slightest sign of ill health. The presence in King Edward of this virus which is not

sap inoculable and so far as we know not conveyed by insects presents a unique problem. Every one of the millions of King Edward plants grown since its introduction twenty-five years ago has been derived from the original single seedling which theoretically at least must have obtained and carried this virus. Whence it was derived and how it gained an entry remain unknown. A solution of this problem might well throw light on the origin of viruses.

TRANSFERENCE OF PLANT VIRUSES

In general the transfer of a virus disease from plant to plant is effected by the intermediary of an insect and in the majority of cases by a sucking insect. Foremost amongst them are the aphids the most catholic of which in its tastes is the peach aphid or *Myzus persicae* which conveys amongst many other diseases leaf roll and leaf drop-streak in potato and mosaic in cauliflowers, and from them carries it to many of our garden flowers. Next come the hoppers which feed in a similar manner to the aphid and are responsible for conveying many very widespread plant diseases such as curlytop in sugar beet streak in maize and yellow aster. Both families of insects are provided with an extremely fine proboscis which inserted between the palisade cells of the leaf penetrates into the fine phloem terminals. Feeding on a diseased plant results in the insect's saliva being contaminated with the virus and the insect on passing to the next plant transfers the disease. If the plant is a healthy one, it may then become infected. Tomato spotted wilt a most infectious disease which readily attacks an enormous and diverse range of host plants is spread by means of a thrips which feeds by a superficial rasping process. The thrips can only pick up the virus when in the larval stage it retains the virus and conveys the disease during its adult life.

An interesting consideration is the degree of specificity displayed between insect and virus in the case of plant and animal respectively. In animal disease a strictly specific relation is rare: that between the body louse and typhus and trench fever seems to be the closest. Dengue while commonly conveyed by the mosquito *Stegomyia fasciata* seems able to make use of two other species on occasions.

In plants we have several examples of a close relationship between vector and virus, such as in curlytop of sugar beet and *Eutettix tenella* aster yellows and *Oncodula sexnotata* streak disease of maize and *Oncodula mabilis* while many others are conveyed by the aphid *Myzus persicae* and one or two closely related aphids. The problem suggested by this close relationship must be left without further discussion as we have no certain evidence as to any developmental relationship between virus and insect.

As to what happens to the virus within the insect is another problem which has not been solved. In some cases an incubation period supervenes which implies some reaction between virus and insect in other cases it is probably a question of mechanical transference only.

Tobacco mosaic and the potato X virus both very infectious, do not appear to have any insect vector. It is interesting that in both these cases spraying with an atomiser a suspension of infected juice on to the leaves of a healthy plant is enough to produce infection.

VIRUS COMPLEX

By a virus complex is meant a disease induced by the combined effect of two or more distinct viruses. The clinical picture that results from this may be

quite unlike that occasioned by the action of either

The following example in potatoes will illustrate it

The virus Λ^G produces no effect on the variety President

The virus A produces at most a slight venal mottle

The combination Λ^G and A produces a severe crippling crinkle

Similarly —

The virus X produces mild mottle or no effect on the variety President

The virus F produces no effect

The combination Λ^G and X^F produce bright permanent interveinal mottle

Similar results arising from the coexistence of two or more viruses can be demonstrated in tobacco

I have found (1932) some evidence that in certain cases in the potato an opposite effect to that described as a result of a virus complex may result. The presence of two or more viruses in the same plant, any one of which would normally produce a serious disease, may result in a reduction of morbid symptoms, the plant being then converted into a carrier. Thung has reported a similar phenomenon in tobacco

TYPICAL DISEASES

Thanks very largely to the work of Kenneth Smith (1936) we have greatly extended our knowledge in the last year or two of the virus diseases of plants both in our gardens and in glasshouses. Reference to his paper (1936b) will open the eyes of some to the fact that their glasshouses and gardens are veritable virus museums. I will only refer to a few of the more outstanding cases

Tomato spotted wilt—This virus is one of the most destructive diseases that affects the tomato. It is carried by the ubiquitous glasshouse thrips and attacks a very large number of plants of many diverse families but even more important is the fact that it is carried or produces but minor symptoms by some. In a commercial house a devastating epidemic has been known to occur as a consequence of the grower keeping a few favourite but infected nasturtium plants in his house from which the thrips spread the infection, a similar danger may arise from infected chrysanthemums. Some of the chief garden flowering plants affected are asters, marigolds, cinerarias, dahlias, lupins, and poppies, whilst in the greenhouse primulas, episcadium, and particularly lilies of the amaryllis type. Weeds such as the dock, the bindweed, and *solanum nigrum* may all serve as centres of infection.

Cucumber Mosaic—This virus, which has been studied for many years in the Cucurbitaceae, is now found to have gained a footing in most gardens. It particularly affects marigolds, asters, delphiniums, and lupins. It produces a flecking or breaking in violas.

Cabbage Mosaic—Cabbage plants of all kinds are most commonly affected with a virus which causes considerable distortion of the leaves and a mottle, on old plants black rings develop and dark green bands along the veins. This virus is frequently conveyed by the aphid, *Myzus persicae*, to stocks and wallflowers, and produces in them a breaking of the flower when infected some of the best of the old self-coloured purples bear only washy streaked flowers.

Mosaic or stripe disease of bulbous plants—Chiefly affects the leaves by inducing light stripes on the leaves of narcissi and daffodils. The flowers often develop a similar streak and all the plants are weakened.

Tulip Break—There are three types of break recognised (1) Full break, in which the basic yellow or white mesophyll tissue is exposed by the withdrawal of the red or purple of the epithelial layer. This is probably due to the interaction of two viruses. (2) Self break, the self colour is intensified producing a streak, one virus only appears to be at work. (3) Clotted break, in which large splashes of intensified colour occur on the petals of the

dark purple shun varieties. The viruses are conveyed by three species of aphids. *Anuraphis tulipæ* which lives on the bulbs and transmits the diseases from bulb to bulb in store, and *Myzus persicae* and *Macrosiphum gei*, which feeding on the leaves convey the disease in the open.

Pelargoniums, especially the varieties Paul Crumpel and King of Denmark, are subject to a disease that causes much spotting and leaf curl in the old leaves. Young leaves in older plants appear to be normal. No vector has been found.

Prevention

It may be asked what protection have we against these subtle virus pests, from whose attacks in plants there is no real recovery. Attempts have been made along several lines which I cannot do more than briefly outline.

Cultivation of naturally immune varieties—These are rare and in general the immunity to be of commercial value must be transferred by appropriate breeding to a newly built up variety. Success has been obtained with the Long Chinese variety of cucumber against cucumber mosaic. The sugar cane industry is to-day built up on two varieties—"Uba" resistant to mosaic and "PoJ 213" resistant to streak. The result has been an enormously increased crop which with our present day economics has resulted in widespread distress.

Cultivation of carriers—This has been, unconsciously, the policy of potato breeding for the last fifty years at least. A good variety is one that reacts but mildly or behaves as a carrier to the more prevalent virus diseases. It is the behaviour of the variety in the second and subsequent year to infection which determines its future utility. No variety withstands all virus attack, nor any that of the Y virus without some, and generally considerable, damage.

Good husbandry—The eradication of weeds, which are in many cases virus carriers, especially the wild *solanum* species, the thorough cultivation of head lands and removal of hedges that shelter insects, above all, the destruction of "ground keepers"—i.e., potatoes or "roots" left in the earth after the harvest—are all of value in keeping crops free from virus infection. Other treatments have been directed against the insect vector. In America large enclosures covered with a muslin of 22 mesh to the inch have been erected over areas as big as 32 square rods. Naturally such inclosures can only be used for special seed crops and need very careful supervision lest they act as forcing houses for aphids. Sprays have been tried but so far as the potato crop is concerned it would need very frequent application of a nicotine emulsion to be effective. Roguing of crops and isolation of special cultures of plants are all used and can be very successful, they are however only practical on a small scale.

Vaccination—A new line of attack on the plant virus problem is being worked out in Cambridge. Following up the discovery that it was possible to vaccinate a plant against a severe virus an attempt is being made to prepare a suitable vaccine against the virus of the disease which troubles us most in the potato field—the Y virus. There is reason to hope that it may succeed. It has already been pointed out that nature herself makes use of protective vaccination in the potato, but that is not her only weapon. It is clear that if there is no focus of dispersion for a virus, there will be no spread. If therefore, a plant is so acutely susceptible to a particular virus as to succumb almost at once, and further it loses all vegetative power in its tubers as if it has any then not only is the patient eliminated but the disease also. This actually occurs in the

case of the potato variety *Epicure* which is at once the most susceptible one of the oldest and most vigorous variety of potato we have

Conclusion

Although the incidence of virus disease in our field and crops and glasshouses has undoubtedly increased there is no reason for undue pessimism. What is needed is more research on virus diseases and a closer understanding between the pathologist and the plant breeder. It is the latter who needs to realise that when by his breeding methods he gives us large and ever larger crops bigger and whiter fruits and the like, he has almost certainly discarded en route a number of hereditary genes which alone or in combination with others may be responsible for that vague but important character—constitution.

MEDICINE AND THE LAW

Unlicensed 'Special Establishment'

LAST December the public control committee of the London County Council revoked the licence of Dr Stavros Constantine Damoglou for carrying on an establishment for massage and special treatment. The decision seemed to be based in part on statements that he represented himself as able to cure blindness in incurable cases. On being notified he disputed the Council's authority; it extended, he maintained to masseurs only and not to persons with medical qualifications. He wrote that he intended to continue to treat his patients by methods of his own invention as he had done for the years 1915 to 1931 without any licence. His patients he said consulted him as their last hope; he would stand by them to bring them hope relief and in many cases complete recovery. Dr Damoglou having preferred to defy the Council rather than to exercise his right of appeal the L.C.C. caused him to be summoned on March 17th at the Marylebone police court. It was admitted by the prosecution that in certain cases of blindness due to nervous disorder the defendant could be very helpful. As a medical man he could carry on his establishment without a licence if he produced a certificate signed by two registered medical practitioners to the effect that he was a suitable person. Dr Damoglou giving evidence said that he was a fully qualified medical man. He protested that his was not a massage establishment.

within the London County Council Act he treated his patients by solar ray and gave them advice upon diet; the great majority received benefit and many were cured. The magistrate imposed a fine of £10 with costs warning the defendant that if he committed the offence again the maximum penalty of £50 would be imposed.

Patient and Radiologist's Report

The Court of Appeal recently discussed the question whether a doctor is obliged to allow a patient to see a radiologist's report. The point arose on the appeal of Mrs. Rubra widow and executrix of Dr Henry Rubra, against the verdict of £5000 damages awarded to Mrs. Connolly for alleged negligence on the part of Dr Rubra in treating Mr. Connolly who died of tuberculosis in 1933. During discussion in the Court of Appeal Lord Justice Slesser referred to Mrs. Connolly's request to see a copy of the radiologist's report. She had received what the judge called a misleading reply. Lord Justice Greene then inquired whether it was the practice in the medical profession not to let the patient see reports of this kind. Mr. Thomas Carthew K.C. appearing for Mrs. Rubra replied that many members of the profession regarded these reports as confidential. It was he added in the discretion of the general practitioner who had sent the patient to the specialist to decide whether the patient should see the report or not. Lord Justice Greer the president of the court, doubted if there was any practice of keeping this information secret much must depend on the doctor's view of the intelligence of his patient. As Mr. Carthew observed a patient is in the hands of his doctor many patients might be seriously upset by being given the information.

The appeal was not concluded before the Easter vacation. When judgment is given we hope to discuss the case further. It has been a striking instance of the risks inherent in the new law when by a personal action now no longer dies with the person concerned. Mrs. Connolly's claim in connexion with the death of her husband was begun while Dr. Rubra was still alive. Dr. Rubra was then in bad health; he died not long afterwards. His widow obtained leave to continue the defence. In denying the allegations of negligence she may well feel that the position of the defence is prejudiced by the death of one who would have been the principal witness on that side.

PARIS

(FROM OUR OWN CORRESPONDENT)

SANATORIUMS OR SANATORIA

THE Anglo-Saxon observation that the French would rather be in the wrong than vague may be reconsidered in the light of a recent discussion in the French medical press over the respective philological merits of *sanatoriums* and *sanatoria*. The indiscriminate and alternating use of both terms in the Anglo-Saxon countries may perhaps be good enough for their natives with their weakness for irrational compromise and inaccurate and nebulous impartiality. The correspondence began with an (as it proved) ill advised attack on a writer who had committed himself to *sanatoriums*. Why had he not given expression to his classical education by writing *sanatoria*? The fat was soon in the fire and it was joined by numerous medical philologists endowed with a classical education spare time, hixographia, libraries and a sense of burning injustice one way

or the other. As a matter of fact, it was practically all one way—the *sanatoriums* had it by an overwhelming majority. It seems that while the adjective *sanatorius* is good Latin, *sanatorium* was coined so recently that it is not to be found in the dictionary of the Academy published in 1878. The 1935 edition of the same dictionary had, perforce, to mention *sanatorium* but added that the plural was *sanatoriums*. The Larousse dictionary hedges by mentioning both plural forms, but of course Larousse is nowhere in the presence of the Academy's dictionary. When the lists have been cleared after this battle, the turn will doubtless come of *serums* versus *sera*.

PATHOLOGY IN STONE

Senlis, which is 33 miles from Paris, has two very interesting museums, one of which contains a collection of some medical interest. It contains more than 300 Gallo-Roman ex-votive offerings representing different

Part of the collection

parts of the body. These were placed by patients before the altar in a temple erected to Mercury which stood close to the town. There are a number of heads, each with an expression of pain, since most of these are heads of women, it is thought that they were

Ex-votive offerings. Models of a foot, breasts and a heart

placed in the temple by sufferers from headache. Breasts, hands, feet, abdominal organs, and even hearts, are among these objects. Archaeologists declare that this collection is superior to the similar collection of ex-votives in Rome.

IRELAND

(FROM OUR OWN CORRESPONDENT)

COLLABORATION BETWEEN HOSPITALS

A GENERAL meeting of the Irish National Association of Hospitals was held in Dublin on March 16th, with Prof. T. G. Moorhead, the president, in the chair. Some forty or fifty institutions were represented. The object of the meeting was to consider the draft memorandum and articles of association. It was soon made clear that some of the representatives present in particular those representing some

of the voluntary hospitals of Dublin, were nervous lest some of the powers proposed to be given to the association should interfere with the independence and autonomy of individual institutions, and various amendments were carried which tended to limit the powers of the association. Agreement was arrived at on the several points raised, and it was arranged that the draft memorandum and articles should be considered again at a meeting to be held in the last week of May. The objects for which the association is established are (a) to maintain an information bureau, (b) to provide opportunities for discussion, (c) to publish papers and reports of conferences, discussions, and proceedings connected with hospital management and administration, (d) to coöperate in any movement for the prevention, treatment, and cure of disease, and for the provision or extension of facilities for hospital treatment, and (e) to undertake any other work that may seem desirable to promote the welfare of patients and those engaged in their care, or the improvement of "hospitals of every description in Ireland or elsewhere." The association, however, is not to make any recommendation in regard to the internal administration of any hospital or in regard to any particular mode of therapy or the treatment of any patient or patients.

THE HOSPITAL SWEEPSTAKES

The twentieth draw of the sweepstakes in aid of the Irish hospitals was held on March 15th and 16th. The gross receipts, and also the proportion available for the hospitals, showed a rise over recent sweepstakes, being in fact the highest since the corresponding sweepstake of 1935. The aggregate sum collected for the hospitals from the twenty sweepstakes is a little over £2,500,000, of which about a third has been disbursed. The retention of so large a sum as £7,000,000 in the hands of the trustees has given rise to a certain amount of criticism. The Government, however, with the aid of the Hospitals Commission, wishes to make a thorough survey of the whole hospital problem in the country, in order that a satisfactory system may be evolved and established, and it is unwilling to allow the funds to be dribbled out prematurely in temporary projects. Moreover it is understood that the Government wishes to make the future maintenance of the voluntary hospitals secure by adequate endowment before it authorises the erection of large buildings. It is clear that hasty action might be dangerous, but it is hoped that the Government may soon make its decision on some of the more urgent parts of the general problem. The increasing pressure on the Dublin voluntary hospitals in particular demands early consideration.

UNITED STATES OF AMERICA

(FROM AN OCCASIONAL CORRESPONDENT)

ADMINISTRATION OF PUBLIC HEALTH SERVICE

RATHER more than a year ago President Roosevelt appointed a committee to examine the desirability of reorganising the executive branch of the federal government. In his message to Congress of Jan. 12th the President presented this committee's report. Among its very comprehensive proposals is the establishment of twelve major executive departments to carry out functions that are now performed by more than a hundred independent agencies, administrations, authorities, boards, and commissions. On

of these departments would be that of Social Welfare to administer Federal health, educational and social activities. Some medical organisations are already protesting against the transfer of the public health service from the Treasury department to such a bureau. They fear no doubt that a medical service would be placed under the direction of some lay social worker. While it is true that a layman who thinks he knows something about public health administration might be a poor exchange for a secretary of the Treasury who knows he knows nothing about it still the service is even now in charge of a lay woman Miss Josephine Roach assistant secretary of the Treasury for whose appointment all public health workers are grateful. The gain to health administration of having all public health functions now scattered through half a dozen different departments gathered under a single department chief would be enormous.

SCHOLARSHIPS FOR PRACTITIONERS

The Commonwealth Fund has published its eighteenth annual report, recording the expenditure

of some two million dollars in accordance with the desire of its founder Mrs Stephen V Harkness to do something for the welfare of mankind. Those in charge of the Fund are strongly persuaded of the value of post graduate education in medicine. Scholarships designed not to make specialists but to enable family doctors to catch up with modern medicine have been granted to 379 physicians to study at Harvard Tulane Vanderbilt and other medical schools. Promising undergraduates have also been given scholarships on the understanding that they enter practice in towns of less than 6000 population.

Thirty-one British university students have been invited to spend two years in the United States as fellows under the Fund. Prof W L Bragg of the University of Manchester has been elected to the British committee of award that selects these fellows. It is said that former fellows have been busy during the past year both in writing about American affairs for British readers and in broadcasting from Great Britain to the United States.

GRAINS AND SCRUPLES

Under this heading appear week by week the unfettered thoughts of doctors in various occupations. Each contributor is responsible for the section for a month his name can be seen later in the half yearly index

FROM A TADDYGADDY

I

Tinker tailor soldier sailor
Rich man poor man taddygaddy thief

"I dressed him and God cured him" So wrote Ambrose Paré, over and again in his case book. What a lot it tells us of the man and in how few words. He was a great surgeon but he was much more than that he was a great doctor. Often when bored or depressed by the importunities of patients and their friends I dip into his book in search of refreshment, and never in vain. There is always something fresh. He was a gentle person a kindly person and he carried in his pocket a pen that could sting: a tool very necessary to him for he was a pioneer in days when pioneers were not popular. Eager for surgical reform he met bitter opposition but he met his critics on more than equal terms. How he did it we can read for ourselves in his description of how he came to realise the ill effects of boiling oil as a dressing for gunshot wounds with his conclusion. Then I determined never again to burn thus so cruelly the poor wounded by arquebuses. That determination it need hardly be said met with the hearty disapprobation of the orthodox the physicians who were very superior indeed the surgeons of the long robe who would not condescend to operate. Paré a barber surgeon was not tied to convention as were those more magnificent ones and felt himself free to attack not only the boiling oil methods but the use of the actual cautery. Confronted by bleeding gunshot wounds he insisted on the use of the ligature in place of red hot irons and was denounced as a surgical heretic. There are some of us who can remember the battles that raged around the question of antiseptics, and later asepsis. They were fierce enough but somehow they lacked the picturesque quality of Paré's controversial style. Perhaps that was fostered by his circumstances. He spent most of his time on or near the battlefield in days

when battlefields were spectacular and for many years he was court doctor during a highly coloured period of history. Catherine de Medici and her sons were his patients. It was owing to her good offices that he, a Huguenot, survived the Massacre of Saint Bartholomew. I like to feel and I think with reason that the friendship existing between Catholic queen mother and Huguenot court doctor was based upon the outstanding honesty and charm of the man.

* * *

Why was it that surgery as Paré found it was so horrifying? For that matter it was horrifying for centuries after him. It is on record that in Italy in the thirteenth century three hundred years before his time *asepsia* was practised and general *anæsthesia* employed. And not only in Italy. Tom Middleton the English poet dramatist, wrote in the very early sixteenth century:

I'll imitate the pities of old surgeons
To this lost limb who ere they show their art
Cast one asleep then cut the diseased part

The doctors had forgotten but the poets had not forgotten. Nor had the common people. What had caused the doctors to forget? That is one of the greater mysteries in the history of our craft. Why did doctoring once gentle become the crude thing that it undoubtedly did? How was it that the nursing sisters of Rahere's foundation gentlewomen living according to religious rule were replaced by those terrible women of whom we may read over and over again right down to the days of Dickens and concerning whom it was found necessary to lay down rules in at least one great hospital forbidding them to drink or dice with their patients? It has been suggested that the Black Death which swept away so many and so much succeeded in submerging medical culture. It is a suggestion worthy of consideration. We know that it affected terribly the members of our kindred calling the clergy. The best of both doctors and priests who stuck to their

posts perished. Those who remained lost the confidence of the people. In Germany so little were the doctors regarded that we find an edict was fulminated compelling plague patients to take the medicine ordered by the doctor or suffer the consequences—suspension on a gibbet, after death, with a coffin. We may smile, forgetting the popular sentiment of that day. That the doctors had “lost face,” as the Chinese put it, is evident. But there was more in it than just that. The best of the doctors were dead. Their teachings were forgotten or went unheeded. Men did actually forget. And of our brethren the clergy it is recorded that there arose parish priests who could not so much as interpret in the common tongue the words of their mass books. The need for men was urgent: the supply of suitable men was just simply not there. As the direct consequence of a great catastrophe ignorance took the place of knowledge.

* * *

For centuries after the coming of the Black Death medicine was a matter of crude ignorant horror. King Charles II, happy during his days of well being with the Spirits of Skull with which he liked to experiment, died slowly under the ministrations of thirteen doctors, all doing something different, and everything unpleasant. Queen Anne's entire family perished. The Princess Charlotte, daughter of that queer person who afterwards became King George IV, was hurried to untimely death by court doctors whose idea of treating a delicate young married woman was to bleed and purge, and then bleed and bleed and bleed. Poor girl, it is no wonder that when her baby came she and it passed out. And even so the orthodox doctors refused to learn. A wise man rediscovered general anaesthesia. He suggested that it might be used to mitigate the pains of childbirth. The orthodox shook their heads and muttered into their beards this and that about “the curse of Eve.” It was the will of God so they asserted, that women should bring forth children in agony. But the Queen, Victoria of blessed memory, knew better. When the next little prince or princess was due she spoke the word. Forthwith she was given the pain destroying essence to sniff. Women owe, and have owed, to Queen Victoria a great deal more than they, perhaps, have ever realised. She overruled the prejudices of the doctors who seemed to think that pain, suffered by others, was a good thing in itself and divinely ordained. She put her foot down hard, as was her

way. No doubt, common sense would have prevailed in any event, but she hurried matters along.

* * *

I feel that we family doctors miss a vast deal by not digging back into the past. We are all panel doctors now, and we assert that we are too busy to read. We leave that to the consulting people of Harley street or wherever it is. It is a poor plea. Harley street has no more leisure, and probably no more inclination, for reading than we have, or ought to have. We G.P.'s (I prefer the old time word, Taddygaddy) have no right whatsoever to shelter behind the excuse of “no time.” We have time for golf, for bridge, for motoring shop—that devasting exercise. Why not time for reading? There is so much worth digging into. How many of us, I wonder, have discovered the *Regimen Sanitatis* of Salerno? It is a storehouse of medical common sense, and was written a very long time ago, nobody knows by whom. Fashioned originally in rhyming dog Latin, there is a rhyming English translation which anybody with a few shillings to spare may buy for himself. It is good for us to read rhyme (I say nothing of poetry), for it serves to remind us of our student days and the rhyming aids to memory which were such very potent helps in time of trouble. Do you remember?

Tamarinds figs prunes and senna,
Cassia pulp and coriander
With sugar water and liquorice
To make the filthy stuff taste nice

That sort of thing. Why it should linger in my memory I have no idea. Nearly fifty years have gone by since I first heard those lines in the materia medica museum of my school. The information they convey is of no conceivable value to me, but the memories they stir are of a value that may not be counted. So with the Salerno rhymes. They tell of a time when the practice of medicine was something to be taken not too seriously when it was very much a matter of joyous common sense.

If thou to health and vigour wouldst attain,
Shun weighty cares—all anger deem profane,
From heavy suppers and much wine abstain
Nor trivial count it, after pompous fare,
To rise from table and to take the air
Shun idle, noonday slumber, nor delay
The urgent calls of Nature to obey
These rules if thou wilt follow to the end,
Thy life to greater length thou mayst extend.

PANEL AND CONTRACT PRACTICE

The London Figures

According to statistics submitted to the London Insurance Committee the number of persons entitled to medical benefit in London at the end of 1936 was 1,901,746 as compared with 1,871,321 in the previous year. During the same period the numbers on the lists of insurance practitioners have increased from 1,774,755 to 1,836,822. The number of practitioners on the committee's medical list was 2162 and the average size of their insurance practices was 842 persons. There were 1063 chemists under contract with the committee at the end of 1936 who are carrying on business at 1204 establishments within the county and 391 outside.

More Dispensing

The cost of providing medicines for insured persons has increased both as a whole and per unit. During 1936 8,006,825 prescriptions were issued in London,

costing £296,391 as compared with 8,561,402 in 1935 costing £279,033. The average cost per prescription rose from 7 82d in 1935 to 7 91d in 1936, the average number of prescriptions per person from 4 85 to 4 99, and the average cost per person from 3s 1 93d to 3s 3 43d. Reference to the table giving the figures from 1927 to 1936 shows that the increase has not been continuous during the decennium. In 1927 8,743,249 prescriptions cost £297,605, the average cost of each of the 4 92 prescriptions per person being 8 17d and the cost per person 3s 4 16d. Comparing these figures with those for 1936 it will be observed that while a quarter of a million or so more prescriptions were issued in 1936 to an insured population approximately 25,000 higher than in 1927, the total cost of the prescriptions was less by something like £1000. The most abstemious year of the period was 1930 when the number of prescriptions was 8,129,035 and the cost £258,522. In that year the average

number of prescriptions per person was 4.31 the average cost per prescription 7.63d and the cost per insured person 2s 8.80d

Prescriptions for insulin numbered 34,027 or 16,276,700 units for an average of 1247 patients per month the total value being £6717

Disallowed Prescriptions

Last year 464 prescriptions were disallowed in respect of articles which were not prescribed appliances and 79 in respect of preparations which do not form part of medical benefit. Of the disallowed articles 51 were finger or thumb stalls 49 were non-scheduled dressings 48 thermogens and capsicum wool 34 glass tubes and rods 25 hypodermic needles (not for insulin) 22 elastic hosiery 20 atomisers inhalers sprays, and the like. The favourite however was eye shades which were disallowed 83 times. Other disallowed appliances were arch supports breast pump corn pads douches forceps funnels hypodermic syringes (not for insulin) litmus paper nipple shield powder insufflator rubber gloves spinal jacket (not according to schedule) spirit lamp

apertum flask syringes temperature charts clinical thermometer trusses vaccination pads and shields and wrist straps. Of the disallowed preparations 29 were for saccharin tablets 17 for charcoal biscuits 13 for casein glycerophosph 0 for virol 3 for roboleine and in addition single prescriptions for fumigating pastilles lactose peptonising powders rennet tablets burnt sugar and shampoo powder. The total value of the 543 disallowed prescriptions was only £38.18s.

Practitioners' Fund

Insurance committees have now been notified of the final apportionment of the Central Practitioners' Fund (England) for 1936 which has been determined at £8,868.85s. London's share of the fund (being 13.1858 per cent) is £337.02s which allows of a distribution of £44,172 over and above the amount provisionally determined earlier in the year. This is nearly £14,000 more than the corresponding sum distributed in respect of the year 1935 and the result will be that London practitioners will receive for 1936 9s 2.63d per unit of credit as compared with 9s 1.17d for 1935.

THE SERVICES

REORGANISATION OF THE INDIAN MEDICAL SERVICES

WHEN provincial autonomy comes into operation on April 1st under the new constitution, considerable changes in the organisation, distribution and terms of service are to be made in the military medical services in India. These are the result of a prolonged investigation extending over more than three years into the whole organisation for both peace and war.

The strengths of the three military medical services in India—the R.A.M.C. in India, the military branches of the I.M.S. and the I.M.D.—will be fixed so as to provide for the minimum medical requirements of British and Indian troops in peace time. There will still be a civil branch of the I.M.S. recruited as hitherto from the military branch and consisting of not less than 220 officers of whom 106 will be British. It will maintain a war reserve on which the Army in India must rely for its increased requirements in an emergency, attend British members of the superior civil services and their families and fill posts under the Central Government and the Crown representative. A new list of posts reserved for I.M.S. officers in civil employ has been adopted involving a reduction from 207 to 172 for British and Indian officers, but the present rights of officers already in civil employment will be fully preserved.

Recruiting for the I.M.S. will still be by nomination on the recommendation of a selection board held four times a year as hitherto. Indian members will be recruited in India and will normally be given short service commissions for five years after which selection will be made for permanent commissions from among those who desire to continue in the Service. British members will be recruited in London and will be appointed to permanent commissions to fill European vacancies.

Revised rates of pay for future entrants have been introduced which will bring basic pay more into accord with Indian standards without materially altering the total emoluments received by British members of the Service who draw sterling overseas pay. At the same time the time-scale of promotion to major has been accelerated throughout by two years. Improvements have also been made in the

rates of pay drawn in the second, third, eleventh and twelfth years of service. An increased outfit allowance of £75 will be granted to new entrants and the maximum period of antedate granted for high qualifications and special experience is raised from 1 year to 18 months.

Six additional colonelcies will be provided on the military side of the I.M.S. and a suitable number of increased pensions equal to those of colonels will be eventually awarded to officers on the civil side.

An officer transferred to civil employment will be on probation for two years. Thereafter he will retain a right to revert to military employment under certain conditions until he has spent 7 years in civil employment or has had 17 years of total service. After this he will if it is agreed that he shall remain in civil employment be transferred to a special supplementary list and will not normally be eligible for military promotion above the rank of lieutenant colonel. This system follows that in vogue for other military officers in civil employ—e.g. in the Indian Political Department.

ROYAL NAVAL MEDICAL SERVICE

The Admiralty announce that the appointment has been approved of Surge Rear Admiral Percival T. Nicholls, O.B., K.H.P., to be Medical Director General of the Navy in succession to Surge Vice Admiral Sir R. W. Basil Hall, K.C.B., O.B.E., K.H.P., to date July 2nd 1937.

Surge Comdr. T. Madill to *President* for course and I. J. A. The O'Rourke to *Drake* for R.N.B.

Surge Comdr. (D) J. L. Edwards to *Drake* for R.N.B. and T. F. Brover to *Drake* for R.N. Hospital, Plymouth; and T. Hunt to *St. Angelo* for R.N. Hospital, Malta.

The following officers qualified at the examination for promotion to Surge Comdr. held recently: Surge Lt. Comdr. F. G. B. Crawford, D.A., Newbery, J. Keovil, F. Dolan, F. W. Besley, and T. L. Cleave.

Surge Lts. (D) L. C. Jenot to *Cangas*; W. A. Dickie and F. S. Roff to *Pembroke* for R.N.B. and W. I. Forrest to *Victory* for R.N.B.

ARMY MEDICAL SERVICES

The Army Council have decided to name the new barracks about to be built for the Royal Army Medical Corps Depot and Army School of Hygiene at Aldershot the "Keogh Barracks" in memory of the late Lieut. General Sir Alfred Keogh, G.C.B., D.C.O., C.H. That

CORRESPONDENCE

INFLUENCE OF SCHOOL ROUTINE ON THE GROWTH AND HEALTH OF CHILDREN

To the Editor of THE LANCET

SIR,—In view of the interest which is being aroused by Mr John Allan's paper in your issue of March 13th, would it not be desirable to quote more fully from the context in the report referred to there—i.e., "The Health of the School Child" for 1935? On pp 12-13, for instance, it is stated that

"The only practical measurements in common use which, so far as we know, can help the assessment are those of height and weight. But stature and weight, though important, may, as was shown last year, by themselves be fallacious guides to the nutritional state, and must be regarded simply as an important part of the evidence to be considered by the medical officer in forming his general impression. Frequent measurements of height and weight are, however, of great value inasmuch as they are the best indices we have of the rate of growth."

The italics are mine, but the extract quoted, and indeed the actual references in the report to weight, height, and growth, and conclusions derived therefrom do not give me the impression gained from it by Mr Allan, that

"estimates of nutritional states are now being based on clinical observations only, standards of height and weight for age being no longer applied."

With regard to the intervals occurring in the increase of height and weight of children which are revealed by more frequent measurement, Corry Mann has drawn attention to this, but he regarded such cyclic or irregular growth periods as normal, and based his conclusions as to progress on observations taken at longer intervals. He evidently associated gain in weight with rest periods, and loss with physical activity.¹ Mr Allan's more minute investigation of

¹ Mann H C C (1926) *Spec Rep Ser med Res Coun Lond* No 105 p 12

these periods, covering 14 years, and their evident association with periods of activity and rest in school environment is therefore particularly interesting, whether or not they are held to be "normal" reactions to the pressure of the child's physical and mental education. As to whether such pressure, at any particular school, is in the long run good or bad for the child needs further investigation. If merely on the lines of physical standards, these would need to be applied at longer intervals, even up to that between the date of entry and leaving school, while such development as increased vital and mental capacity are not necessarily accompanied by linear growth or increase in weight, and yet they may be accepted as evidence of cause and effect of an improved nutritional state.

As to children in one school being more stunted than in another, this can and should be verified by applying age height standards, but it is certainly expedient to observe the parents before seeking a cause in the school routine. There is an example of such a high proportion of small children in a day school near London. The parents are of small stock, and the grandparents are migrants from the north. There is also a type of child known to the children's hospital as the "Austin 7" feeding it with gland extract or milk does not convert it into the "Rolls Royce" type.

As these small children can and do become efficient people, and more pathological forms of dwarfism occur before school entry, it seems that, beyond securing the stimulus afforded by milk, it is most practical to take the height attained as the basis for other measurements, and if the height weight standards are to be applied, they should be correlated by some reference to cross section, of which chest circumference is a rough expression. It can be easily shown that with equal sitting height, weight varies directly with chest circumference, and thus is evidently only

THE SERVICES (continued from previous page)

very distinguished officer was Director General Army Medical Services from 1905 to 1910 and again during the war from 1914 to 1918.

The following changes are announced—

Col H H A Emerson DSO, was promoted supernumerary Major General on March 26th and will continue in his appointment at the War Office as Director of Hygiene.

Col J W L Scott, DSO was promoted to Major General on March 26th, and leaves the War Office to be Deputy Director of Medical Services Eastern Command.

Major General FitzGerald, CB, DSO, vacated medical charge at Horse Guards on March 26th.

Col F Casement assumed the post of Deputy Director General Army Medical Services on March 26th.

Col S W Kyle is the new Assistant Director General at the War Office.

The War Office announces that applications are invited from medical men for appointment to commissions in the R.A.M.C. Candidates will be selected for commissions without competitive examination, must present themselves in London for interview about April 22nd, and normally must not be over the age of 28. Successful candidates will be given short service commissions for five years and then may apply for a permanent commission. Those not selected will retire with a gratuity of £1000. Particulars and forms of application may be obtained on application either by letter or in person to the Assistant Director General Army Medical Services the War Office London SW 1.

SURGICAL BRUCELLOSIS

To the Editor of THE LANCET

SIR—On my return from South Africa I have read with great interest Dr J I Edwards's report in your issue of Feb 13th of a case of fixation abscess of bone due to brucella. This is the first case of what might be termed surgical brucellosis occurring in this country of which I have heard but there are many reports in the literature of such occurrences in the Mediterranean area due to infection with *Brucella melitensis* and there have been a few such reports in recent years in connexion with both the *melitensis* and *abortus* varieties of brucella. Thus Botreau Roussel and Huard reported in 1931 a case of osteomyelitis of the lunate bone of the wrist in a soldier of 20 probably due to *Br. melitensis* the infection having been acquired in the course of a local epidemic of undulant fever in man and abortion in goats in the village of La Souche (Ardèche). Hardy Jordan and Borts reported in 1936 a series of cases of undulant fever in Iowa which included osteomyelitis of various long bones and one of the small bones of the wrist. Griliches reported a case in 1930 from Switzerland in which the patient, a farmer of 20 developed a small abscess on the dorsum of the right foot from which *Br. abortus* was grown in pure culture.

It is interesting in this connexion to note also that local abscess formation in the conditions known as poll-evil and fistulous withers are quite common in horses in America Germany Holland and other countries, and pure cultures of *Br. abortus* are usually grown from these local abscesses.

ERGOTAMINE TARTRATE IN MIGRAINE

To the Editor of THE LANCET

SIR—As a very great sufferer in past days from this dyscrasia, I suggest to Dr Kelly and warn your readers to put no trust in drugs or at present any product from a laboratory. Years ago I asked a distinguished physician now in the shades how about your migraine? He dramatically replied: Better. I have passed the change of life. I am well on in the seventh decade and can answer as he did. The change begins in the mid fifties. I believe the only remedy is: a dark well ventilated room long drinks of water and with 5 minute occasional intervals, a 24 hours sleep. The outstanding point of this procedure is, there is no drug aftermath.

I am Sir yours faithfully,

W BURNOUGH COSENS

Tunbridge Wells March 30th

To the Editor of THE LANCET

SIR—From my personal experience of the relief of migraine headache by ergotamine I can add one small point to those enumerated by Dr Kelly. In my own case I was for several years almost incapacitated for three days every fortnight since taking Femerin hypodermically about 60 attacks have been aborted with no failures. The attacks however are more frequent than they used to be.

I have found that the beneficial effect of the drug is aided by taking food at the same time. Whereas

when I first used femergin I frequently had to repeat the dose in 1-2 hours to stop the attack, I now find that one dose is enough if food is taken at the same time

I am, Sir, yours faithfully,

ELIZABETH L. FLEMING

Upper Wimpole street W, March 29th

HYPOGLYCAEMIC SHOCK IN THE TREATMENT OF SCHIZOPHRENIA

To the Editor of THE LANCET

SIR—Being partly responsible for the introduction of hypoglycaemic shock for schizophrenia into this country and the first to use it here, I welcome Dr Russell's clear cut article in your last issue (p 747),

and agree with his conclusions. Eleven cases have been treated at the Royal Edinburgh Mental Hospital since March, 1936, and in the 526 periods of hypoglycæmia no alarming incidents have occurred. In certain cases of prolonged coma there is deficient absorption of the glucose feed by the stomach, when larger amounts of intravenous glucose should be given. In my experience after shock is only likely to occur when more than 1 ccm of adrenaline has had to be given, or when the patient has refused his ordinary meals after the feed. Smoking should not be permitted until one hour after the feed, as it tends to precipitate the hypoglycaemic symptoms, or cause a return of these.

I am, Sir, yours faithfully,

Edinburgh March 28th

H PULLAR STRECKER

PARLIAMENTARY INTELLIGENCE

FACTORIES BILL IN COMMITTEE

THE Factories Bill was further considered by a standing committee of the House of Commons on March 23rd.

DA NGEROUS CON DITIONS

On Clause 38 (which provides that if on complaint by an inspector a court of summary jurisdiction is satisfied that any part of the works, machinery, or plant used in a factory is in such a condition, or so constructed, that it cannot be used without risk of bodily injury, or any work is carried on in such a manner as to cause risk of bodily injury, the court may prohibit the use of that part of the factory or prohibit its use until it is repaired or altered, or require the owner to take steps for remedying the danger) Mr SILVERMAN moved an amendment providing that the clause should be mandatory instead of permissive by leaving out the word "may" and inserting the word "shall". He said that the court should not be left with discretion in the matter of making an order where they were satisfied that an offence had been committed.—After discussion, Mr LLOYD said it did not make any difference whether the word "shall" was inserted, though he feared that it would not have the result expected by supporters of the amendment.—The amendment was agreed to.

Mr RHYS DAVIES moved an amendment to leave out "danger to life" and to insert "risk of bodily injury". Under the clause as it stood he said the court would only be entitled to make an order if the inspector was satisfied that a workman was about to be killed. He wished to enable the court to make an order when an inspector was satisfied that a workman was liable to bodily injury.—Mr LLOYD said that a tremendous power was given under the clause and it should be circumscribed within proper limits. He accepted the broad principle, but the amendment went too far. He thought it would be better if they made the amendment read "risk of serious bodily injury".—The amendment was agreed to in this form.

On Clause 39 (Power of court of summary jurisdiction to make orders as to a dangerous factory) Mr RHYS DAVIES said that amendments had been put down on danger to health. He wished to know whether the interpretation of "bodily injury" in the interpretation clause included injury to health.—Mr LLOYD: Yes, Sir, that is included in the definition clause.

DRINKING WATER

On Clause 40 (Supply of drinking water) Mr BURKE moved an amendment to provide that when the supply of drinking water did not consist of a drinking jet there should be provided and maintained at every point of supply a reasonable number of clean drinking vessels. He said that those who had experience of factories knew how very inadequate the

provision often was for the supply of water to the workpeople, and realised the advisability of ensuring that in addition to the water-supply being adequate the drinking vessels themselves should be kept clean. He would prefer that instead of having any drinking vessels at all there should be at suitable points in the factory a basin with a jet of water. That ensured cleanliness for everyone using the jet. It would be better in many cases for the workers to go thirsty all day rather than use over and over again, one after another, one dirty can which they could not wash properly, unless they washed it in the water they were going to drink. From the health point of view he felt that this clause was weak and might be easily strengthened at very small cost.

Mr LLOYD said he agreed with the mover of the amendment that it was important to have proper supplies of drinking vessels. In his experience he much preferred the jets. Provisions rather similar to those contained in the amendment were inserted in the Drinking Water Welfare Order which wide application to factories, but not to all, particularly not to small factories. In this Bill term factory applied to something which they had not always been accustomed to regard as a factory, but rather as a workshop. A dressmaker's establishment with a dressmaker and one assistant actually a factory under this Bill. They had to be careful to consider such small places as that. While accepting the principle he could not accept the wording of the amendment. He would suggest that the amendment should read "Except where water is delivered in an upward jet, from which workers can conveniently drink, one or more suitable cups or drinking vessels shall be provided at every point of supply with facilities for rinsing them drinking water". The last part was intended apply to small establishments.

Mr BURKE withdrew his amendment in favour of the amendment suggested by Mr Lloyd.

CLEANLINESS

On Clause 41 (Washing facilities) Mr BURKE moved an amendment the object of which he was to extend washing facilities to every factory in the country.—Sir E GRAHAM-LITTLE said that it was not only in the factories where dirty and offensive materials or processes were used where washing required. It was just as essential in factories where cleanliness was of paramount importance in processes, such as in the preparation of food. great factory in Chicago the employees who packed sandwiches were actually manicured before going into the factory. If the Under-Secretary accepted the requirements of this amendment would move that the word "cleansing" should be substituted for the word "washing".—Mr BURKE said that food was being prepared in all kinds of and canned or bottled in many factories, and tremendous advantage of suitable washing facilities.

had been proved in the packing industry. As a result of consultation with the Home Office a Washing Facilities Order was issued and led to vast improvement both in the food trade itself and in benefit to the men and women engaged in the industry.—Mr. WELSH said that he wished the committee could see the changes that had taken place in the miners and particularly the young men as a result of the provision of pit baths.

Mr. LLOYD said that the Government accepted the view that the provision of washing facilities was very important as a general question in view of the rising standards of life of our people. But there were certain difficulties involved. Washing facilities were provided under the Dangerous Trades Regulations and Welfare Orders and a considerable number of industries were covered. This clause was really an attempt to carry these processes further by giving a quicker method of extending washing facilities to other industries; but after listening to the discussion that day he thought that the matter ought to be considered with a view to bringing forward wider proposals. He could not accept this amendment at that stage. This was an expensive part of the Bill. It would not be reasonable to require in every case the provision of elaborate washing facilities if they were not really going to be used. If the amendment was withdrawn he would undertake to go into the matter before the report stage with a view to widening the proposals in the clause.

The amendment was negatived.

Mr. SMITH secured an amendment that a sufficient supply of soap and clean towels conveniently situated should be provided under the clause.

On Clause 42 (accommodation for clothing) Mr. MANDER moved an amendment to provide that the clause should apply to all factories. He said if work people came to a factory no matter what the processes were that were carried on, and they were soaked through with rain facilities should be provided for drying their clothing before they went home.—Mr. LLOYD promised to look into the matter before the report stage.—Mr. VIANI said that many men working on buildings for example were compelled to work in very inclement weather. They ought not to be expected to work in wet clothes. Rheumatism was extraordinarily prevalent in the building trade, and he hoped that the Under-Secretary would try to meet this difficult point.—The amendment was withdrawn.

FIRST AID

On Clause 44 (First aid) Mr. BROAD said that as drawn the clause only provided for first-aid boxes in factories where mechanical power was used. He moved an amendment to remove that limitation. There were many dangerous operations in places where no mechanical power was used and minor injuries might lead to major trouble such as septic poisoning. It would be no burden for employers in factories without mechanical power to make such elementary provisions for first aid as could be found in any decent home in the country.—Mr. LLOYD said that in this case as in an earlier one which the committee had discussed they had to remember that the Bill covered very small establishments. Would it be reasonable to require the provision of a first aid box in a dressmaking establishment with one principal and an assistant? According to Home Office records there were small establishments where accidents occurred rarely or were unknown. In cases where dangerous operations took place in factories without mechanical power undoubtedly first aid boxes ought to be provided. But they could be required under the Bill through the safety or welfare regulations and he could assure the committee that in any such case the Home Secretary would require the provision to be made.—After further discussion Mr. LLOYD promised to look into the matter further and the amendment was withdrawn.

Mr. J. GRAHAM LITTLE moved an amendment to provide that the first-aid boxes should be examined

annually by a factory surgeon. He said that the inspection of first-aid boxes was as necessary as the inspection of fire appliances and they should be inspected as well as used by a competent person.—Mr. LLOYD said the Home Office did not think it was really necessary that the first-aid boxes in factories should be examined by a surgeon. The contents of the boxes were prescribed in detail by the Secretary of State under orders and therefore it was an easy matter for the factory inspector to make certain that the right ingredients were in the boxes.—Sir E. GRAHAM LITTLE replied that it was not so much the right ingredients as their condition. It was the aseptic character of the dressings which was required and that could not be estimated by simple inspection.—Mr. LLOYD said that that was a matter which he would consider further. The Home Office considered that the factory inspectors were capable of checking the contents of the boxes and he was advised that there was not much risk of deterioration of the contents for a reasonable period. He would however look further into the question of the aseptic part of the dressings. With regard to the qualifications of those who applied the first aid that again was a question of distinction between very small workrooms and large factories. It was conceivable that in a large factory it might be a reasonable requirement to have someone proficient in first aid although he was advised that a responsible person which was the term used in the Bill should be capable of dealing with most of the minor first-aid assistance which was necessary. He would however reconsider the question with a view to making some distinction between large factories where it might be reasonable to have someone experienced in first aid and cases where it would not be reasonable.

The amendment was withdrawn.

AN AMBULANCE ROOM IN EACH FACTORY

Mr. RHYES DAVIES moved an amendment to ensure that where more than 150 persons were employed in a factory a suitably equipped ambulance room should be provided and such arrangements should be made as to ensure the immediate treatment there of all injuries occurring in the factory. He said that there was always a danger unless there was an ambulance room where an injured workman could be properly treated that septic poisoning would set in. It was an astonishing fact that in this country for some reason he did not know whereas the health of the community had improved enormously the statistics of sickness and disablement arising from injuries showed an increase every year. His view was that speeding up had something to do not only with the rate of sickness but with the number of small accidents which were constantly occurring. He hoped that the Home Secretary would look with a kindly eye on this amendment.

Sir JOHN SIMON said that he looked on this amendment with a great deal of sympathy; the only question was the best way of doing it. When they came to the end of this clause they would have made provisions under which welfare regulations could be made dealing with ambulance and first-aid arrangements. Already under the existing factory code welfare orders had been made by the Home Office which required an ambulance room. The point about which he felt some doubt was whether they should lay it down in the Statute that where there were 150 workpeople there should be an ambulance room. He was advised that the question did not depend on the number of the workpeople. He urged that the better way of dealing with the matter was by welfare orders.

The amendment was withdrawn.

BUILDING IN SCOTLAND

In reply to a question by Mr. MATTHEWS in the House of Commons on March 23rd Mr. ELLIOT, Secretary of State for Scotland said the meetings had been held with representatives of employers and operatives representing practically all the organisations.

tions in the building industry in Scotland, at the first of which he was himself present. Information has been placed before the building industry showing the approximate amount of public work (including houses, schools, hospitals, &c., and building for defence requirements) that it is desired to carry out within the next few years. The representatives of the industry were asked to examine and consider whether the available supply of skilled labour in the different trades was sufficient to enable the various programmes to be carried out, and, if not, to suggest methods by which the supply could be increased. The representatives of the industry were prepared to make recommendations designed to secure such progressive increase in the number of skilled operatives as might be necessary, provided that assurances are given of reasonable continuity of employment. Under the provisions of the Housing (Scotland) Act, 1935, the Exchequer contributions at the present rates are payable for houses completed by March 31st, 1938, and the question of the rates for the three years immediately following that date must be reviewed in consultation with the associations of local authorities after Oct 1st this year. In view of the importance to local authorities of knowing what their financial position will be after March 31st, 1938, it was his intention, said Mr Elliot, to submit proposals to Parliament for the continuance of the present rates of Exchequer contributions under the Housing (Scotland) Act 1930, and the Housing (Scotland) Act, 1935, for the three years beginning on April 1st, 1938, that is to March, 1941. The Government were closely watching the position in regard to supplies and prices of materials, and will keep in touch with local authorities and producers in the matter. He was arranging, Mr Elliot added, for meetings with the associations of local authorities to discuss the question of planning these building programmes so as to ensure the maximum degree of continuity of progress. When these negotiations were concluded there would be made possible a marked improvement in the recent rates of house building by local authorities, and that as further operatives become available the rate could be progressively expanded.

Replying to further questions Mr Elliot said that the arrangement did not involve the abrogation of trade union rules, and that the present rate of assistance would be guaranteed for the lifetime of this Parliament.

NOTES ON CURRENT TOPICS

Cardroom Workers and Respiratory Illness

In the House of Commons on March 25th Mr STURGEON asked the Home Secretary whether he was now able to announce the names of the committee to be appointed to inquire if a workable scheme could be devised for providing compensation for cardroom workers disabled by respiratory illness. — Sir JOHN SIMON replied: Yes, Sir. The following is a copy of the Warrant of Appointment of this committee:—

I hereby appoint Mr W. D. ROSS OBE, M.A., LL.D., D.Litt., Mr P. N. HARTY, F.I.A., Mr T. HUTTON, Prof. GLOUCE R. MURRAY, M.D., FRCP, and Mr W. F. WACKRILL OBE, to be a committee to consider and report whether an equitable and workable scheme can be devised for providing compensation in the case of persons who after employment for a substantial period in cardrooms or certain other dusty parts of cotton spinning mills become or have become disabled by respiratory illness as indicated in the Report of the Departmental Committee on dust in cardrooms and, if so, to make detailed recommendations as to the provisions to be included in such a scheme, more especially as to the persons to whom benefit should be payable and the rates and conditions of benefit; the medical and other machinery for administering the scheme, the method of financing the scheme and its approximate cost. And I further appoint Dr W. D. ROSS to be chairman and Mr C. P. COURLEY to be secretary of the committee.

In the House of Lords on March 23rd, the Marquess of DUFFERIN AND AVA introduced a Bill to provide for the regulation of the fumigation of premises and articles by hydrogen cyanide. The Bill was read a first time.

In the House of Lords on March 23rd the Public Health (Drainage of Trade Premises) Bill was read the third time and passed.

In the House of Commons on March 23rd Mr BALDWIN, Prime Minister, presented a Bill to regulate the salaries payable to those holding certain Administrative Offices of State. It provided additional salaries for members of the Cabinet holding offices at salaries less than £5000 a year, a salary to the existing Prime Minister, pensions to those who have been Prime Minister, and a salary to the Leader of the Opposition. It also simplified the law about the capacity of those holding offices of profit to sit and vote in Parliament. The Bill was read the first time.

In the House of Lords on March 24th the Deaf Children (School Attendance) Bill passed through Committee. The House of Lords adjourned for the Easter recess on March 24th until April 7th. The House of Commons adjourned on March 25th until April 6th.

QUESTION TIME

TUESDAY, MARCH 23RD

Sickness and Ill-health in the Army

Mr SORESENSEN asked the Secretary of State for War how many were discharged from the Army through sickness and ill health during 1936, and how many of these received or would receive, either pensions or some kind of financial assistance. — Mr DUFF COOPER replied: During 1936, 1786 men were discharged from the Army Reserve as invalids. I regret that the information asked for in the second part of the question is not available but during the year referred to 1800 new applications for disability awards were preferred. Pensions, permanent and temporary, were awarded in 398 cases, and gratuity in 813 cases.

Slow-burning or Inflammable Films

Mr DAVY asked the Home Secretary whether in view of the changes that had taken place in the film producing industry since the case of the V.P. Pier (Folkestone) Syndicate, Limited, versus Reeve, which was decided in 1912 with reference to the meaning of slow-burning or non inflammable films, and the co-operation among local licensing authorities as to the application of same to present-day sound films, he would consider the appointment of a departmental committee to consider these difficulties and to advise and enable him to introduce legislation to clarify the position. — Sir JOHN SIMON replied: I do not think it necessary to appoint a departmental committee, as I propose to refer the question of slow burning or non inflammable films to an ad hoc committee on the Cinematograph Act, 1909, which I right hon. friend, the Secretary of State for Scotland, I am in process of constituting.

Mining Explosions in Britain and France

Mr ROWSON asked the Secretary for Mines if he could give comparative figures showing the number of explosions in the British mining industry and the French industry, and the number of persons killed in such explosions during the last 15 years. — Captain CROOKSHANK replied: There may be some doubt whether the figures are strictly comparable but they indicate that the French record in regard to explosions is proportionately so better than our own that the French Government has asked to give facilities for an investigation to be made of any differences in their conditions or practice. Investigators will be Major Hudspeth, Deputy Inspector of Mines, and another officer of my department, and they will leave for France as soon as the necessary arrangements can be made with the French Government. The following is a statement showing the number

explosions and the number of persons killed thereby at mines under the Coal Mines Act in Great Britain and at coal and lignite mines in France during the years 1920-1934

Year	GREAT BRITAIN		FRANCE	
	Explosions involving death	Persons killed	Explosions involving death	Persons killed
1920	16	20	3	4
21	17	19	4	25
22	14	73	3	5
23	10	60	2	0
24	18	35	1	1
25	11	20	1	1
26	6	5	1	2
27	11	72	4	13
28	16	38	—	—
29	13	34	4	36
1930	18	70	—	9
31	12	107	—	—
32	13	69	—	—
33	8	35	—	—
34	11	96	—	—

Note—Owing to the absence of detailed particulars of each separate accident in the case of France, there may be a few cases in which death was due to asphyxiation without an explosion having taken place

Grants for Slum Clearance

Mr WILFRID ROBERTS asked the Minister of Health whether a final decision had been reached as to whether or not housing grants for slum clearance would be payable after March 31st 1938, and whether only houses actually completed by that date would be eligible for Government grants.—Sir KINGSLEY WOOD replied: Under Section 109 of the Housing Act 1936 I am called on to review after Oct 1st 1937 in consultation with the Local Authorities the Exchequer contributions payable for slum clearance and the abatement of overcrowding. The section provides that contributions at the existing rates will be payable for houses completed by March 31st 1938. Local authorities will soon be letting contracts for houses which will not be completed till after that date and I have received a number of representations on the matter.

The completion of slum clearance and the abatement of overcrowding are vital elements in the health services of the country. I am anxious to preserve the continuity in this housing programme and to avoid the disturbance which might result from a position of uncertainty. I have therefore given some preliminary consideration to the matter. I cannot under the statute carry out my review or submit proposals to Parliament till after Oct 1st 1937 and these proposals must be made in the light of the facts as they then exist. When I do submit proposals it is my intention to include among them provisions under which the now existing rates of Exchequer contribution will continue without alteration for houses built in replacement of unfit houses or for the abatement of overcrowding which are completed by Dec 31st 1938.

Model Diet in Mental Hospitals

Mrs TATE asked the Minister of Health in how many mental hospitals in England and Wales the model diet for an entire four week period had been introduced as recommended in the 1924 Report of the Departmental Committee on Diets in Mental Hospitals.—Sir KINGSLEY WOOD replied: I understand a number of mental hospitals have adopted a dietary for a four week period though I am not aware of the exact number. The matter is determined by the visiting committee of the local authority and generally upon the advice of the medical superintendent. I am advised that the standards recommended by the committee on Diets in Mental Hospitals have been generally adopted.

WEDNESDAY MARCH 24TH

Medical Research in East Africa

Mr MATTHEWS asked the Colonial Secretary whether any steps had been taken as to the result of the recommendation of the Conference on the Co-ordination of the General Medical Research in East Africa that research should be directed to the social and economic development of the African

should be undertaken by the Medical Research Council.—Mr ORRISBY GORE replied: I assume that the hon Member is referring to the report of the conference held in January 1936. The recommendation of that conference was not that research be undertaken by the Medical Research Council but that in order to help if it was decided to make an application for funds a body of experts should visit East Africa. The report was examined by the Tropical Medical Research Committee of the Medical Research Council and by the Colonial Advisory Medical Committee who advise me that they doubt whether any useful purpose would be served by such a visit and that further assistance could best be rendered by the visit of individual experts to study special problems as they arise. I regret that at the present time there are no funds available from which such a scheme of further research could be financed and I observe from the Report of the Conference that the minimum sum required for their scheme was stated to be at least £30,000 or £40,000 a year.

Medical Certificates and School Meals

Mr MORGAN JONES asked the President of the Board of Education whether he would make arrangements whereby local education authorities could delegate to headmasters and headmistresses of schools authority to give meals to necessitous children without waiting for a certificate from the medical officer of the authority.—Mr GEOFFREY SHAKESPEARE, Parliamentary Secretary to the Board of Education, replied: I am sending the hon Member a copy of the Board's Circular 1443 from which he will see that there is no requirement that a certificate should be given by the school medical officer before children may receive free meals. It is for the local education authority to decide whether children should be fed and in paragraphs 4 and 5 of the Circular they are urged to invite reports from school medical officers, teachers and others in regular contact with the children from day to day and to make interim arrangements pending full investigation for the immediate feeding of children recommended for meals.

THURSDAY MARCH 25TH

Spirochætal Jaundice Order

Mr WIDSON asked the Home Secretary whether he was now prepared to make the necessary order for the scheduling of spirochætal jaundice as an industrial disease, as recommended by the Home Office Committee.—Captain MARSHALL, Parliamentary Secretary to the Treasury, replied: The drafting of this order has been found to raise some points of difficulty which are being gone into but my right hon friend hopes that the matter will be settled at an early date.

Drunkenness in Armament Areas

Sir ROBERT YOUNG asked the Home Secretary whether in view of the increased drinking and drunkenness in some towns concerned in the new measures for national defence and in particular in Warwickshire where a chief constable had drawn attention to the considerable increase of drunkenness and disorderliness since the drinking hours were lengthened he would call for an inquiry into the influence of the various kinds of extended drinking facilities upon public order and industrial efficiency, especially in the armament manufacturing areas.—Captain MARSHALL replied: The grant of extended drinking hours lies generally speaking in the discretion of the local justices who can be trusted to take due account of all relevant circumstances in their locality. My right hon friend does not think that there is any ground for the institution of such an inquiry as is suggested by the hon Member.

Infectious Diseases Hospital for Retford and Workop

Mr BELLINGHAM asked the Minister of Health whether he had yet approved a scheme for the provision of an infectious diseases hospital for the urban and rural districts of Retford and Workop.—Sir KINGSLEY WOOD replied: The scheme of the Nottinghamshire County Council for the provision of adequate hospital accommodation for the treatment of infectious diseases in that county was

approved by me on Oct 10th, 1935 I have since received from the local authorities concerned applications for provisional orders for the establishment of joint hospital boards for that part of the county in which the districts to which the hon Member refers are situated These applications are under consideration

Appointments under Midwives Act, 1936

Mr VIANI asked the Minister of Health if, when issuing regulations in connexion with the Midwives Act, he instructed the medical officers of health when making appointments to confine such appointments to those who possessed a certificate in midwifery and also the certificate of a State registered nurse—Sir KINGSLEY WOOD replied The Midwives Act, 1936 does not empower me to issue regulations with regard to the qualifications of midwives to be appointed under the Act In the circular which I addressed to local supervising authorities on Sept 18th last I drew attention to the importance of absorbing into the new service as many as possible of the independent midwives, at present in practice, and the circular made no suggestion that appointments should be confined to midwives who are State registered nurses I should deprecate any such limitation in the case of the appointments first made by local supervising authorities under the Act

Prepared Fruit Juice

Mr DE LA BERE asked the Minister of Health whether he was aware that cases existed of manufacturers who made synthetic or semi synthetic products labelled as genuine fruit juice, or prepared fruit juice, which contained no foundation of real fruit, and whether he would take steps to prevent such misdescription—Sir KINGSLEY WOOD replied On the facts as stated it would appear that the matter can be dealt with by the responsible local authorities under the Food and Drugs (Adulteration) Act, 1928 and I do not think therefore, that any special action on my part is necessary

Indictable Offences

Mr SHORT asked the Home Secretary the number of persons found guilty of indictable offences during 1935 and 1936, respectively, the number of juvenile offenders, and how the latter were dealt with—Sir JOHN SIMON

replied The number of persons found guilty in 1935 of indictable offences was 69,849 Of these offenders 25,643 were under the age of 17 Of the offenders under the age of 17, 9 per cent were sent to Home Office Schools 51 per cent were placed under the supervision of a Probation Officer, 8 per cent were bound over without an order for supervision, and 24 per cent were dismissed Figures for 1936 are not yet available

Health Insurance and Medical Treatment

Sir ROBERT GOWER asked the Minister of Health if, taking the figures for the last five years, he could state the average number of insured persons who had never used the services of their panel doctor—Sir KINGSLEY WOOD replied In each of the five years 1932 to 1936 the number of insured persons in England and Wales who, although entitled to medical benefit had not chosen an insurance doctor was on the average about 495,000 I cannot give a similar figure of the number of persons who have chosen a doctor but have not used his services

Clinics for Mental and Nervous Diseases

Mr RHYS DAVIES asked the Minister of Health how many clinics were operating, under the control of his department or the Board of Control, for persons suffering from incipient mental or nervous diseases, together with their location and availability—Sir KINGSLEY WOOD replied I am having this information compiled and will send it to the hon Member as soon as possible

Ministry of Labour versus a Manchester Hospital

Mr ELLIS SMITH asked the Minister of Labour whether he had considered the report by the Manchester Royal Infirmary Medical Board on the building which the Ministry of Labour intended to erect adjoining the central branch of the Manchester Royal Infirmary, and what action he proposed to take—Mr E BROWN replied I would refer the hon Member to the reply given on this subject on March 8th—Mr SMITH Has the Minister considered the very serious report prepared by the medical board, and, if he has, will he give his personal attention to this matter in order that satisfactory arrangements can be made between the two parties?—Mr BROWN I am giving my personal attention to this matter

PUBLIC HEALTH

A Five-Year M and C W Scheme for London

ON April 1st comes into operation the scheme by which the L C C and the councils of the metropolitan boroughs make a fixed contribution for the next five years to the voluntary associations providing M and C W services in the county of London The four largest annual contributions are these North Islington infant welfare centre, £4310, Royal College of St Katharine infant welfare centres, £3860, Violet Melchett infant welfare centre, day nursery and mothercraft training home, £3535, Salvation Army mothers' hospital, £3034. The conditions attached to the grants are that the council shall be satisfied of the efficiency of the services provided and that a reasonable number of the persons are using them, that no reduction or alteration of the services shall be made without the consent of the council, that the premises are open to inspection at all reasonable times and that a copy of the annual report with a statement of accounts and auditor's certificate shall be sent each year to the council On the other hand the council may not terminate or reduce the annual contribution without the consent of the Minister of Health, and any dispute or difference between the council and a voluntary association must be referred to the Minister whose decision shall be final

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK END—
MARCH 20TH, 1937

Notifications—The following cases of infective disease were notified during the week Smallpox, 1 (Derby), scarlet fever, 1791, diphtheria, 1068, enteric fever, 24, pneumonia (primary or influenzal), 1288, puerperal fever, 37, puerperal pyrexia, 115, cerebro spinal fever, 25, acute poliomyelitis, 3, acute polio-encephalitis, 1, encephalitis lethargica, 8, dysentery, 20, ophthalmic neonatorum, 90 No case of cholera, plague, typhus fever was notified during the week

The number of cases in the Infectious Hospitals of the London County Council on March 26th was 3305 which included: Scarlet fever 862, diphtheria 1041, measles 26, whooping-cough 568, puerperal fever 18 mothers (plus 10 babies), encephalitis lethargica 232, poliomyelitis 1 At Margaret's Hospital there were 15 babies (plus 6 mothers) with ophthalmic neonatorum

Deaths—In 122 great towns, including London, there was no death from small-pox or enteric fever, 10 (1) from measles, 1 (0) from scarlet fever, 21 (1) from whooping-cough, 30 (4) from diphtheria, 45 (1) from diarrhoea and enteritis under two years, 171 (21) from influenza The figures in parentheses are those for London itself

Birmingham reported 6 deaths from measles Hull 2, 1 case of whooping-cough were scattered over 15 great towns Liverpool and Middlesbrough had each 3 Fatal diphtheria was reported from 26 great towns Liverpool and Birmingham each 3 Deaths from influenza have slightly increased Birmingham reported 10 Leeds 7 Sunderland and Cardiff each 1 The number of stillbirths notified during the week was 281 (corresponding to a rate of 41 per 1000 total births), including 51 in London

OBITUARY

JOHN DAVID MALCOLM M.B. F.R.C.S. Edin.

The death occurred on Saturday March 20th, suddenly at Sheet House Petersfield, of Mr John David Malcolm in his day a well known obstetric surgeon. The son of Dr John Malcolm of Edinburgh he received his medical training at the University of Edinburgh and Guy's Hospital and graduated as M.B. Ch.B. Edin. in 1881 taking later the diploma of F.R.C.S. Edin. He held the resident appointments at the Royal Infirmary Edinburgh and then decided to practise as a specialist in London. He made a considerable mark with careful reports of clinical work contributed to the *Transactions* of the Medical and Chirurgical Society the Medical Society of London and our own columns. He was elected to the staff of the Samaritan Free Hospital, was president of the obstetric and gynaecological section of the Royal Society of Medicine was awarded the Liston Victoria Jubilee prize of the R.C.S. Edin. and gained a high position in his specialty as a careful and successful operator. He had retired from the medical profession for a considerable time and was approaching his eightieth birthday at the time of his death.

Dr Cuthbert Lockyer sends us the following appreciation. With the death of John Malcolm there now remain only two of the eleven men who made up the staff of the Samaritan Hospital at the end of the last century. In 1898 which dates my own connexion with that institution the staff was composed of five physicians and six surgeons. The physicians were Drs. Boulton Routh McCann Roberts, and Tate. The surgeons were Messrs Merodith Doran Malcolm, Butler-Smythe, Targett and Corrie. Keep and the distinction which then existed between physician and surgeon was one of vested interests. The activities of the former were confined to vaginal surgery whilst to the latter came all the laparotomies. The anomaly of this arrangement was emphasised by the fact that the academic surgical qualifications of the physicians (as exemplified by possession of the F.R.C.S. Eng.) were higher than those of the surgeons. A certain struggle for equality was animated and Mr Malcolm as one of the privileged surgeons, finally acquiesced in the removal of an anachronism. When the late Mr H. Targett retired in June 1899 I took his place and thus became assistant to Mr Malcolm. This meant helping at all his operations at first in hospital and only later in private as well. This relationship continued for a few years only. It lasted long enough however and was sufficiently intimate for me to appreciate the value of a training which in its austerity was obsolete at the present day but which none the less, I should have been sorry to miss. Those were the days when the principle of total isolation for abdominal cases was insisted on and accordingly laparotomy was only carried out in small rooms containing one, or at most two beds each. There was no resident officer and the assistants duties embraced the functions of house surgeon and porter combined whilst the nurse in immediate charge in operation-cases would remain on duty continuously for more than 48 hours. In 1896 Mr Malcolm was granted seven surgical beds and if I recollect rightly these were distributed among half a dozen small rooms. In 1905 the number of his beds was increased to eight.

Malcolm had inherited many of the attributes of

his predecessor and master Knowsley Thornton including a certain brusqueness of demeanour which whilst alarming at first was found later to be only a surface-display and became far less evident as time went by. Looking back after a lapse of more than a quarter of a century one recalls Malcolm as a colleague who merited respect for his outspokenness and his honesty of purpose for his indomitable energy and perseverance for his loyalty to and willingness to help a colleague, and even for his pertinacity in opposition. It would be safe to say that he had no enemies among his hospital colleagues and this may be explained because we always knew what was to be expected of him. At the Samaritan the governing body induced him to continue his services beyond the age limit of 60 years and it was universally felt that the reputation of the institution was enhanced by his services. His death will be accounted a severe loss not only by his old colleagues who survive him but by all those with whom he came in contact at the Samaritan and at the Royal Society of Medicine.

JOHN ARNOLD JONES O.B.E. M.B. Vict., F.R.C.S. Edin.

We regret to announce the death of Dr Arnold Jones at the age of 57 which occurred suddenly on March 23rd. He had been in poor health for some time past following a severe illness last winter, but recently had seemed much better and his sudden death came as a great shock to his relatives and many friends.

Arnold Jones was a Manchester student and obtained the degrees of M.B. Ch.B. in 1903. After a post as house surgeon to the Manchester Royal Infirmary he successively held residential posts at the Royal Ear Hospital London and the Birmingham and Midland Ear and Throat Hospital. By this time he was well on the way to taking up his specialty and supplemented his education in that branch of surgery by a period of study in the Viennese clinics. He held the posts of honorary surgeon to the St. John's Hospital for Diseases of the Ear and Throat honorary assistant to the Royal Manchester Children's Hospital and to the St. Mary's Hospitals. From his early student days Jimmy Jones was recognised as a fluent speaker and a keen debater and many an otherwise dull evening has been enlivened by his shafts of wit and repartee. He was a man of very strong opinions which he never hesitated to express and if his views sometimes aroused opposition they invariably attracted attention and were a fruitful source of discussion. In his own branch of surgery he soon became an authority both as a clinician and an operator and his contributions to his subject were always listened to or read with attention. During the war he served with the 26th General Hospital in Salonika where he was appointed consulting aural surgeon and laryngologist to the British Expeditionary Force. He was awarded the O.B.E. for his services and retired with the rank of major.

No man had a wider circle of friends made in his youth and retained with increasing affection as the years passed by. Ready for any fun which might be afoot in his younger days Jones was the life and soul of the party. Always an omnivorous reader he leaned upon this as a recreation more and more as time passed but to the end nothing gave him greater joy than a reunion with his old friends. His death is a personal loss to his many friends all of whom

will unite in offering their sympathy to his widow and two children

"C P L" and "H T A" write "Arnold Jones, or 'Jimmy,' as he was affectionately known to his colleagues, during his long period of service at the Royal Manchester Children's Hospital, was punctilious in the performance of his duties, and very successful in dealing with children. His mastoid operations were particularly successful. He paid special attention to the after care of his patients, and never spared himself in their service. As a mark of the appreciation of his services he was elected a member of the board of governors. He was a man of strong opinions, fearless in his support of them, and a loyal friend who will be much missed by his patients, both private and hospital, and by his colleagues, many of whose children had been under his care."

MABEL PAINE, M B Lond

We have received the following graceful and pathetic tribute from Prof Harold Balme to Dr Mabel Paine, who died in a Surrey nursing home on Easter Monday

"Born in Maidstone in 1874, Mabel Paine joined the London School of Medicine in 1892. She graduated at London University in 1900, held resident posts at the Elizabeth Garrett Anderson Hospital and Chelsea Infirmary, and then took up general practice in Kensington. During this period she became interested in infant welfare work, and also became clinical assistant at two of the chief hospitals for diseases of the chest. In 1917 she commenced consulting practice and was appointed assistant physician to the Elizabeth Garrett Anderson Hospital. Four years later she was made a full physician, but in 1927, when at the height of her work, her health gave way, and after struggling on heroically for some months she was at length compelled to give up her practice and resign her appointments.

"During the severe illness which followed the nobility and beauty of her character fully revealed themselves. For over eight years she lay an invalid, battling against an insidious renal infection which racked her strength with recurrent attacks of pyrexia and pain and defied every resource of medical and surgical science. Throughout this wearisome time her courage, patience, and keen scientific interest in every new form of therapy endeared her to nurses and doctors alike, whilst her richly stored mind made her companionship a source of constant profit and delight. Old patients from all parts of the country came to visit her, each testifying to the depth of affection they bore her and the debt they owed to her personality and skill. 'The humblest woman God ever made' was the description given of her by one of her patients, whilst a former colleague recently spoke of her as 'the gentlest of spirits and soundest of opinions.' Her life and her influence will ever be fragrant memories to all of us who had the privilege of her friendship"—H B

HERBERT ANDREW, M B Edin

Dr A H T Andrew, who died at Holbrook, Suffolk, on March 22nd in his 54th year, was born at Northampton, educated at Bedford Modern School and St Edward's School Oxford and pursued his medical studies at Edinburgh University where he graduated in 1910. Although a good footballer, holding a regular place in the University Rugby fifteen, he was even in his undergraduate days a

student of nature, spending much of his spare time in observing, photographing, and stuffing birds. He already loved his gun, rod, and artist's brush. After holding resident hospital appointments in Edinburgh, Dublin, and Northampton, he settled in practice at Leiston Suffolk, where he remained for fifteen years. He held a commission in the Territorial Army and on the outbreak of war in 1914 was attached to the 1st East Anglian field ambulance and served through the Gallipoli campaign in the famous 29th division. He was transferred with that division to France, where he belonged to the 88th Field Ambulance and was also for a time attached to the 1st Royal Inniskilling Fusiliers. In 1917-18 he worked in the casualty clearing zone, first as an anaesthetist, but finally realising his laudable ambition of being appointed a surgeon, in that capacity he worked in the 53rd Clearing Hospital till the armistice. In 1927 he relinquished his practice at Leiston, but remaining faithful to the county of his adoption transferred to Holbrook, where in addition to his ordinary work he became medical officer to the Royal Hospital Naval School, an appointment which he held till his death.

A war time friend and comrade writes "Two years of almost constant association with Andrew as a tent fellow cemented a friendship that death alone can destroy, and although mileage precluded frequent meetings in the years of peace, I retain a vivid memory of a debonair officer, no matter how depleted of sleep and rest, indefatigable, self sacrificing, and the best companion in a surgical team that any surgeon could desire. His affability and charm enhanced our popularity as a visiting team to other clearing stations in times of battle. His fortitude was shown in his final illness. At a graveside last week the huge concourse would have surprised one who was himself so modest, it was a tribute to the matchless worth of the general practitioner. The corner of Suffolk between Stow and Orwell has been robbed by death of a devoted doctor and a great gentleman."

Dr Andrew married Ethel Rosamond Candy and leaves a widow and six children

JOHN ATTLEE, M D Camb

Dr John Attlee, who died on March 8th Wellingborough, was the son of the late John Attlee of Dorking. He was educated at Amersham School and St John's College, Cambridge, and graduated with honours in the Natural Sciences Tripos in 1888, proceeding for his medical training to St Bartholomew's Hospital with the Shuter scholarship. He graduated as M B, B Chir Camb in 1892 and did useful research work under the late Prof Kanthack. He had clinical appointments at his hospital, at Hospital for Consumption, Margaret street, and at Royal Westminster Ophthalmic Hospital, and from the outbreak of war until 1919 he held the post of ophthalmic surgeon to the Victoria Hospital for Sick Children. Dr Attlee practised in the Grosvenor square district for more than forty years before his retirement last October and his personal qualifications no less than his professional skill contributed to his all round success. He made certain contributions to medical literature of a practical nature and was always deeply interested in development either in theory or treatment.

Dr Attlee was 67 years old at the time of his death and is survived by a son and a daughter.

MEDICAL NEWS

University of Cambridge

Dr S. D. Elliott has been appointed university demonstrator in the department of pathology.

The following have been appointed examiners for the diploma in medical radiology and electrology: Mr Q. Stead and Mr B. L. Wormop Ph.D. (Part I). Dr F. Roberts Dr Russell Reynolds and Dr E. P. Cumberbatch (Part II).

University of London

At a recent examination the following candidates were successful:—

D.M.B.

Part I.—I. A. Abou Sima, Pranasanthi Arunachalam, C. B. Chatterjee, Phyllis M. Fraser, D. W. Smithers, and R. C. W. Stalor.

Applications for grants from the Thomas Smythe Hughes fund for assisting medical research are invited in our advertisement columns. They should reach the academic registrar of the university by May 15th.

Society of Apothecaries of London

At recent examinations the following candidates were successful:—

Surgery—O. L. Blacklock, Univ. of Camb. and Guy's Hosp.; K. G. Pascale and R. A. Stenhouse, Guy's Hosp.; H. G. Stitt, Westminster Hosp.; G. Theophilus, Univ. of Oxford and St. George's Hosp.; R. H. S. Thompson, Univ. of Oxford and Guy's Hosp.; T. Van Der Walt, London Hosp. and W. W. Wilson, Univ. of Oxford and St. Mary's Hosp.
Medicine—V. M. Attenborough, Roy. Free Hosp.; E. M. Attenborough, Roy. Free Hosp.
Midwifery—W. J. Bold, Westminster Hosp.; E. E. Bullock, Univ. of Leeds; E. S. Reed, Univ. of Camb. and St. Mary's Hosp.; J. J. C. Smith, London Hosp.; G. Theophilus, Univ. of Oxford and St. Mary's Hosp.; W. W. Wilson, Univ. of Oxford and St. Mary's Hosp. and W. G. Zerab, Guy's Hosp.

The following candidates, having completed the final examination, are granted the diploma of the society, entitling them to practise medicine, surgery, and midwifery: C. L. Blacklock, R. G. Stitt, G. Theophilus, and W. W. Wilson.

University of Leeds

At recent examinations the following candidates were successful:—

M.D.

L. Glick, E. H. Kitching, L. Nagley, A. B. Raper, and J. F. Warrin.

FYNAL EXAMINATION FOR M.D. CH.D.

Part I.—J. A. Braham, T. E. Broadbent, D. Brook, W. L. Carruthers, J. Cross, J. K. Drucquer, D. B. Feather, Dorothy Hain, E. Hyman, E. W. Jackson, W. R. Jackson, R. A. Keighley, E. S. Levy, S. Madden, Kathleen V. Miller, R. Orton, J. Oulton, G. J. Field, J. E. Robinson, J. W. Scholey, S. H. Sordman, M. St. George, I. B. Stewart, A. W. Taylor, A. P. B. Walnd, A. J. Ward, T. I. Watkins, D. O. Williams, Kathleen Wilson, and K. B. Wood.
 Part II.—K. B. Anko, A. A. Driver, R. W. Ellis, V. P. George, I. R. Gray, G. A. Green, G. W. V. Greig, T. Hardy, Gwyneth M. Hosking, K. H. Husain, S. Laak, R. Lawrence, A. Livingston, Agnes M. Mitchell, P. P. Raper, J. A. Rhind, A. H. Rhodes, Joyce M. Rhodes, I. D. Riley, C. H. Robinson, G. B. Robinson, H. S. Sordman, J. C. T. Sykes, D. Taverner, G. Thelwell, L. G. Toham, Mary Townsend, Lella M. Walman, J. W. Walker, and F. J. D. Webster.
 Part III.—J. A. Rhind (first-class honours), A. A. Driver (first-class honours), R. W. Ellis (first-class honours), I. R. Gray, G. W. V. Greig, I. D. Riley, and D. Taverner (second-class honours), Rosemary Blackwood, R. W. Ellis, T. Hardy, Gwyneth M. Hosking, K. H. Husain, S. Laak, R. Lawrence, N. Livingston, Agnes M. Mitchell, P. P. Raper, A. H. Rhodes, Joyce M. Rhodes, C. H. Robinson, G. B. Robinson, I. D. Riley, C. T. Sykes, L. G. Toham, Lella M. Walman, W. Walker, and F. J. D. Webster.

FYNAL EXAMINATION FOR D.C.H.D.

K. M. Newbould (second-class honours).

FYNAL EXAMINATION FOR L.D.S.

P. R. Davidson, R. M. Dent, A. D. Halliwell, H. H. Hammond, P. H. Popen, E. H. Sanderson, A. Stannard, J. O. Sykes, and Walmsright.

D.P.H.

A. D. B. Broughton.

British College of Obstetricians and Gynaecologists

The following candidates have satisfied the examiners and have been awarded the diploma of the College:—

Mr R. Anderson, W. G. Baker, R. G. Barton, Jane O'Brien, S. Dawne, W. General, R. E. Henson, C. W. C. Jarran, May, R. J. L. Miller, G. J. Min, F. M. Newham, C. C. Newham, Margaret F. Robertson, Sophie Schiller, and Phyllis Dorothy M. Stewart and Clifford Tellow.

Royal College of Physicians of London

An additional Prophit scholar will shortly be appointed to cooperate with the present scholar in the conduct of a survey into the incidence and progress of tuberculosis in selected sections of the community. Special experience in tuberculosis is not essential. Applications should be sent to the assistant registrar of the College, Pall Mall East, London S.W.1 before April 26th. Further particulars will be found in our advertisement columns.

King's College Hospital

Sir Walter Langdon Brown will address the Listerian Society at this hospital on Wednesday April 7th at 8.15 p.m. He will speak on the integration of the endocrine system. Medical students and practitioners are invited to attend.

Radiological Congresses

The twenty-eighth congress of the Deutschen Röntgen Gesellschaft will be held at Breslau from April 12th to 14th. Further information may be had from Prof. Erik Brückner, 22, Berlin, N.W. 87. It is also announced that the International Radiological Congress will be held in Chicago from Sept. 13th to 17th.

Institute of Medical Psychology

On April 20th, 21st, and 22nd Prof. E. Kretschmer of Marburg will lecture at the institute, Malet-place, London W.C. at 8.30 p.m. He will speak on heredity and constitution in the etiology of psychic disorders on the structure of the personality in relation to psychotherapy and on instinct and hysteria. The lectures are open only to medical graduates and tickets may be obtained in advance from the educational secretary of the institute.

Royal Navy Medical Club

The twenty-third annual dinner of this club will be held at the Trocadero Restaurant, London W. on Friday April 16th, at 8 p.m. The general meeting will take place before the dinner at 7.30 p.m. Information can be had from the hon. secretary, Surgeon-Commander M. B. Macleod R.N., Medical Department, Admiralty, London S.W.1.

Demonstrations of Contraceptive Technique

On Wednesday April 7th at the C.B.C. clinic at 3.30 p.m., a practical demonstration of the technique of the use of a variety of contraceptive methods will be given by Mrs. Marie Stopes D.Sc. and Dr. Evelyn Fisher. Tickets may be obtained in advance from the hon. secretary, 108 Whitfield-street, London W.1.

Dickinson Scholarship Trust

This trust which is administered by representatives of the Manchester Royal Infirmary and the University of Manchester awards an annual scholarship in anatomy of £25 an annual travelling scholarship in medicine of £300 and in alternate years a scholarship in pathology and surgery of £75. The scholarships are open to graduates of any university who have received the three last years of their medical training at Manchester. The increased present-day costs of living and travelling have made it necessary to supplement the travelling scholarship and the trustees are appealing for additions to the endowment. The fund may be addressed at the Royal Infirmary, Manchester.

Vitaminised Margarine

At a meeting of the food group of the Society of Chemical Industry on March 10th in London Mr P. N. Williams speaking on the food value of margarine said that during the last fifty years it has been shown that both margarine and the fats used in making it are almost completely used by the body. It is nearly twenty years Mr Williams continued since Halliburton and Drummond drew attention to the almost complete absence from margarine of certain vitamins normally present in good butter. Vitaminised margarine was placed on the market for the first time ten years ago. To-day the great bulk of margarine—in Great Britain at least—is a completely vitaminised in respect of vitamins A and D.

Battersea General Hospital

At a recent meeting of the board of management Sir Harold Bellman, managing director of the Abbey Road Building Society, was elected chairman of the hospital, and the names of Mr G J Sophian, F.R.C.S., and Dr John Speares were added to the membership of the board

St George's Hospital

A donation of £8000 has been received by this hospital from the executors of the late Mr Caleb Diplock of Eastbourne. The gift is to be devoted to providing and equipping two operating theatres in the new hospital.

The hay fever clinic which was inaugurated last year has reopened. Patients will be seen each week day, and the medical staff numbers 10, but as 500 applications for treatment have already been received no more can be considered at present.

World Congress on Mental Hygiene

The second world congress on mental hygiene will take place in Paris from July 19th to 23rd under the auspices of the French League for Mental Hygiene. Scientific sessions will be held in the morning and afternoon, and a number of visits to mental institutions and clinics are being organised. Attendance at the congress is open to all interested in mental hygiene. Copies of the preliminary programme and all particulars may be had from the secretary of the National Council for Mental Hygiene, 76, Chandos House, Palmer street, London, S.W.1.

International Short Wave Congress

The first International Short Wave Congress will be held in Vienna from July 12th to 17th under the presidency of Prof A d'Arsonval, Marchese Marconi, and Prof J Zenneck. There will be an exhibition of the newest inventions and their practical application. The official languages will be English, French, German, and Italian. The work of the congress will be divided into the following sections: physics, chemistry and physical chemistry, and technical physics, biology, and medicine. The secretariat of the congress may be addressed at the physical medicine department of the Allgemeines Krankenhaus, Alserstr 4 Vienna, IX.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES**ROYAL SOCIETY OF MEDICINE**, 1, Wimpole street W 1

Connaught Hosp. Watlington Ave.—Med. Reg. Also Cas. O. at rate of £175 and £100 respectively

Dorchester Dorset County Hosp.—H.S., at rate of £150

Dudley Guest Hosp.—Second H.S. £120

Durham County Council.—Asst. School M.O. £200

East India Hospital, Singapore.—Gen. Res. M.O. £3.00

Kretling Hosp. for Sick Children, Southsea S.E.—H.S. at rate of £120

Glasgow Royal Faculty of Physicians and Surgeons.—Fellowship in Clinical Medicine

Guilford Royal Surrey County Hosp.—Asst. Pathologist, £200

Guy's Hosp. S.E.—Clin. Asst. for Radiology Dept., at rate of £150

Hampstead General and A. N. London Hosp. Harcourt Hill, N.W.—H.S. at rate of £105

Harrogate Children's Laboratory.—Clinical Pathologist £450

Harrogate, Royal Bath Hosp.—Res. M.O., £150

Hosp. for Sick Children Great Ormond-street W.C.—Out patient Med. Reg. £175

Hull Royal Infirmary.—Second H.S. at rate of £150

Leeds General Infirmary.—Res. M.O. for Maternity, £250

King's College Hosp. Denmark Hill S.E.—Sen. and Jun. Asst. Radiologists

Lancashire County Council.—Consultant Obstetrician, £1000

Leeds Public Dispensary and Hosp.—Cas. O. and H.S. £10

H.P. each at rate of £160

Leeds University School of Medicine.—Demonstratorship in Department of Physiology

Leicester City General Hosp.—Res. M.O. at rate of £200

Leigh Infirmary, Lancs.—Jun. H.S. at rate of £150

Lincoln County Hosp.—Jun. H.S. at rate of £150

Lipkoot, Hants. King George's Sanatorium for Sailors.—Asst. M.O., at rate of £200

Liverpool Royal Children's Hosp.—Res. H.S. for City Branch at rate of £100

Liverpool Royal Infirmary.—Registrar to Orthopaedic and Fracture Dept., £200

Liverpool Royal Southern Hosp.—H.S. to Orthopaedic Dept. at rate of £100

Liverpool Sanatorium Delamere Forest Frodsham.—Sen. Asst. to Med. Supt. £350

London and Counties Medical Protection Society Ltd Victory House Leicester-square, W.C.—Secretary, £150

London County Council.—Asst. M.O. A, Grade I, £350. Also Asst. M.O. A Grade II, £250

London Hosp. A.—First Asst. to Gynaecologist and Obstet. Dept., £250. Also First Asst. to Neuro-surgical Dept.

London County Council, St. Stephen Green, P.—Asst. Anaesthetist 11 guineas

London Lock Hosp. 223, Harrow-road W.—Res. M.O. to Male Depts., at rate of £175

Manchester General Infirmary.—Second H.S. at rate of £150

Manchester General Hosp.—Radiological Officer £200

Metropolitan Hosp. Kingsland-road E.—Sen. and Jun. H.P.s at rate of £100. Also Cas. O. and Res. Anaesthetist each at rate of £100

Midland Children's Royal Riding Infirmary.—Cas. O., at rate of £150

Newark General Hosp.—Res. H.S. £175

Newport Mon. Royal Gwent Hosp.—H.P. at rate of £150

Also two H.S.s, each at rate of £135

North Devon County Hosp.—H.S. at rate of £150

North Devon County Hosp.—Res. M.O. £150

Nottingham and Midland Infirmary.—Res. H.S. £200

Nottingham General Hosp.—H.S. to Spec. Depts., each at rate of £150

Orkney Island &c. Central Pacific.—Asst. M.O. £250

Othman Royal Infirmary.—H.S. Also H.S. to Spec. Depts. each at rate of £175

Oxford Hospitals.—Morris Orthopaedic Hosp. Headington.—H.S. at rate of £100

Paddington Green Children's Hosp. W.—H.P. and H.S. each at rate of £150

Pembury, Cassel Hosp. for Functional Nervous Disorders.—Two Locum Tenens each 8 guineas a week

Plymouth Prince of Wales's Hosp. Devonport.—Jun. H.S. at rate of £120

Portsmouth and Southern Counties Eye and Ear Hosp.—H.S., £160

Portsmouth Royal Hosp.—H.S. at rate of £130

Reading Royal Berkshire Hosp.—H.S., Cas. O. and H.S., to Spoo. Depts. each at rate of £150

Radcliffe Hosp.—Hon. Anaesthetist.

Royal Cancer Hosp. Fulham-road S.W.—Second Asst. Pathologist, £250

Royal Cancer Hosp. City-road E.C.—Med. Reg. £50

Royal College of Physicians Pall Mall East S.W.—Prophyl. Scholar £100

Royal College of Surgeons of England W.C.—Election of Professors and Lecturers

Royal Naval Medical Service.—M.O.s

Royal Victoria Hosp. for Children &c. Waterloo-road S.E.—Res. Cas. O. and H.P., at rate of £150 and £100 respectively

Salisbury General Infirmary.—Res. M.O., £250

St Albans and St. Marks Hosp., Church-crested.—Res. H.S. £150

St. Mary's-on-Sea Buckham Hosp.—Jun. H.S. £12.5

St. Mary's Hosp. for Women and Children Platonia E.—Res. H.S. and Res. H.P. at rate of £155 and £130 respectively

Scarborough New Hospital.—Two H.S.s, each at rate of £130

Sheffield General Hosp. for Women.—H.S. at rate of £100

Sheffield Royal Hosp. Post on Res. Med. Staff at rate of £20

Sheffield University Dept. of Bacteriology.—Asst. Bacteriologist and Demonstrator £500

Shrewsbury Royal Salop Infirmary.—Res. H.S. at rate of £100

Somerset County Council.—County M.O.H. and School M.O., £1500

Southampton Royal South Hants and Southampton Hosp.—Hon. Ophth. Surgeon

Stoke-on-Trent Burton Haywood and Tunstall War Memorial Hosp.—Res. H.P. at rate of £150

Sunderland Royal Infirmary.—Cas. O. £150

Sussex, East Hosp. Connaught Place Park-road.—Res. M.O. at rate of £200

Trafford Royal Cornwall Infirmary.—H.S. £170

Warrington General Hosp. Medical School, W.C.—Belt Memorial Fellowship for Medical Research £400

West Bromwich, Hallam Hosp.—H.P., at rate of £200

Western Ophthalmic Hosp. Margate-road W.—Jun. Res. H.S. £100

Wigan General Hosp. &c.—M.O.H. and School M.O., £200

Wickford Essex, Turner's Hosp.—Asst. Res. Physician £250

Wolverhampton Royal Hosp.—H.S. at rate of £100

Worthing Hosp.—Ophthalmic Surgeon.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Bamber (Wolverhampton), Bockingham (Bent) and Dorchester (Dorset). Applications before April 6th

Births, Marriages, and Deaths

BIRTHS

COWTIN.—On March 27th at Plymouth the wife of Dr W. H. Cowtin, Kingsbridge, of a son.

GALLOWAY.—On March 24th at a Nottingham nursing-home the wife of Dr V. P. R. Galloway M.B. of a daughter.

GRAHAM BIRCH.—On March 20th, at West Hildbury, Manchester the wife of Mr. Alexander Graham Bryce J.R.O.S. of a son.

HEDDERLEY.—On March 21st at Winchester the wife of Dr E. H. Valpy Hedderley of a daughter.

McDONNELL.—On March 8th at Gravesend, the wife of Dr O. McDonnell of a daughter.

O'CONNOR-CURRY.—On March 19th at Eastbourne the wife of Mr. Desmond O'Connor-Curphy F.R.C.S. of a daughter.

WALKER.—At Chowlands, Haindon Gate, Co. Durham on March 8th to Dr and Mrs. G. F. Walker—a son.

YOUNG.—On March 20th at Esher the wife of Dr Matthew Young of a son.

MARRIAGES

DAVIES.—ALLEN.—On March 25th at St. James's Paddington J. O. F. Davies, M.B. to Margaret P. Allen, of Toronto.

DRANE.—PETER.—On March 10th quietly, at St. Mary Bolton, London H. H. Drane Major-General M.B. ret., to Margery elder daughter of the late Mr. and Mrs. J. K. Pepper.

FLITCHER.—FRANKS.—On March 22nd in London. Ernest Fletcher M.D., to Mary Louise Franks of Heston Farm, Bellingham Kent.

KENDRICK.—LOXLEY.—On March 22nd, at the Church of the Holy Name, Esher, Captain G. W. Kendrick, R.A.M.C. to Patricia Andrea eldest daughter of the late Duke Hanolph Young O.B.E.

DEATHS

ANDREW.—On March 2nd, Alfred Herbert Trebman Andrew M.B. Edin.

BENNETT.—On March 9th at Watford, Frederick Joseph Bennett M.R.O.S. Fnc. L.D.S.

GRATEY.—On March 28th James Burnett Gratey M.R.C.S. Eng., of Hamstead Common road E. 8. aged 70.

McKENNAN.—On March 21st Mr. and Mrs. J. K. Pepper.

MICHERSON.—M.D. M.D. F.R.C.O. Emeritus Professor of Midwifery in the University of Aberdeen.

NASH.—On March 28th, at Hampton Hill, William Gunter Nash M.B. Edin., L.S.A., late of W. Yorks. Northants, aged 83.

STURROCK.—On March 27th, Evelyn Lanesborough Alexander Corbett Sturrock M.D. Edin., M.R.C.I. Lond. J.I.

WHITTINGTON.—On March 29th at Hove Rd. hant Whittington, M.D. Oxon.

V.D.—A fee of 1s. 6d. is charged for the insertion of Notices of Births, Marriages and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

ANCILLA'S REGISTER

THE Board of Registration of Medical Auxiliaries was set up last May, and the following representatives were appointed to its council: Mr H S Souttar, F.R.C.S., Dr G C Anderson, and Dr C B Heald (British Medical Association), Mr Vernon Cargill, F.R.C.S., and Group Captain H Cooper, M.R.C.S. (Society of Apothecaries of London), Mr R C Elmslie, F.R.C.S., Miss E W Bliss, and Miss E M Humble (Chartered Society of Massage and Medical Gymnastics), Mr H J Fde, Dr D D Malpas, and Mr F Melville (Society of Radiographers), Mr A W Ormond, F.R.C.S., and Mr E G Harwood (Association of Dispensing Opticians). The object of the board is to maintain a comprehensive register of those engaged in services ancillary to medicine. The first issue has now been published.¹ It consists of three sections—one giving the names of physiotherapists arranged topographically, and the second the names of dispensing opticians similarly arranged while the third is an alphabetical list of all the names which refers the reader to the appropriate local list. The board is not a qualifying body and at present recognises the examinations of the Chartered Society of Massage and Medical Gymnastics, the Society of Radiographers, the Association of Dispensing Opticians, and the examination for biophysical assistants of the Society of Apothecaries. But the claims of other bodies are being considered and the scope of the register may be widened to include them in the future. Those whose names are on the register have signed an undertaking not to do medical work except under the direction of a medical practitioner, and doctors are urged to make the fullest possible use of the register. A copy of it will be supplied on request free of charge to any registered medical practitioner.

A DOCTOR IN THE COUNTRY

IF the publishers of Dr Philip Gosse's pleasant digressions² from the theme of going for a walk—in the country—had consulted the calendar when they fixed on April 1st for the date of its issue they might have made efforts to get it out before Easter, for it is the sort of holiday reading that makes cold days indoors a delight instead of a penance. He writes entertainingly as ever on Park Brown, the most venerable spot in Sussex, on Sussex Saints and others, on birds in folk lore, in books, or in cages, on angling, and on leaving things alone. In the two last chapters entitled *Foreigners*, *Innkeepers*, *Journalists*, and *Sportsmen*, *Nudists*, and *Naturalists* some of the prejudices and tastes indicated in Dr Gosse's contribution to our *Grains and Scruples* columns last autumn are effectively underlined. To the list, given in an appendix of those among the great array of books about Sussex which have given pleasure to the author of this one, we would by his leave add another—"The Four Men" by Hilaire Belloc—which no lover of the county can afford to miss.

SUICIDE IN MENTAL HOSPITALS

A PAINSTAKING study of asylum suicide is described by Dr Eric Backlin who has examined the records of all the Swedish State asylums for 1901-33 (*Hygiea* Feb 15th 1937 p 65). The total was 159—only 18 of the victims were women—and though analysis by three-year periods shows a considerable increase this is accounted for by an equivalent increase in the number of patients under care. The size of the hospital did not seem to affect the suicide rate,

but this was highest in those where the average duration of the patients' stay was shortest—no doubt because these deal largely with acute psychoses. While the suicide rate outside asylums generally rises with age, it reached its maxima in the Swedish State institutions at 30-35 for men and at 30-35 and 45-50 for women. The large majority of the patients had previously betrayed suicidal inclinations at one time or another, and the fact that they were not under continuous observation was in some cases the fault of the hospital personnel. Backlin concludes that "without a well-trained staff, all other precautions are more or less worthless. But the work of the staff may in this respect be considerably lightened by certain local and administrative measures."

PSYCHOLOGY AND THE CHILD

Prof Sachs's achievement in neurology commands respect for his opinions, but a series of essays on the child³ will hardly enhance his reputation as a psychologist. The essays on infancy, school truancy, and adolescence are benevolent and commonplace. They tell us little more about the child's upbringing than any intelligent, well-balanced parent already knows himself. Page after page is devoted to good natured moralising, until suddenly the kindly author of the first eighty pages becomes the vitriolic opponent of everything that psychoanalysis has discovered and the guidance of children that a knowledge of it might suggest. Everyone realises that, taken at its face value, psychoanalytic theory is not only unpalatable but difficult to comprehend by those who have not studied it at first hand. It is unfortunate, however, that one who should write with authority has clearly not given to the theory the attention it deserves and the objective criticism that it merits at this stage in the history of psychopathology.

HIGH WALL

IT is rare for novels about private mental hospitals to ring true. The details in a book with the title⁴ appear to be based on first-hand knowledge, and, if it were not for the author's note asserting the contrary, those familiar with American institutions would be inclined to identify the place described. It is questionable whether there is much basis for the publisher's opinion that the theme of the book will interest the psychiatrist: the clinical details in the account of a young man who has an acute psychosis and subsequently forgets that he has murdered his wife are rather improbable. If the experiences of this patient in the Tri-State Sanatorium where he and a nurse fall in love with one another that are the main theme of the novel which will probably make a greater appeal to the lay public than to the doctor.

A DIRECTORY OF NURSING HOMES.—We have received from Benn Brothers Ltd (154, Fleet-street, London, E.C.4) a copy of the seventh edition of directory of nursing and convalescent homes, nursing homes, &c., in England and Wales and Scotland. The directory gives the names and addresses, arranged under counties of all registered nursing homes of the several classes of patients, and it is stated that the information has been obtained either from the home itself or from some responsible official source or both. The book which contains 280 pages, well bound in cloth and costs 4s.

ADDRESSES AND ORIGINAL ARTICLES

PATHOLOGY OF THE ADRENAL GLAND
IN RELATION TO SUDDEN DEATH*

By C. KEITH SIMPSON, M.D. Lond.

ASSISTANT LECTURER IN FORENSIC MEDICINE AT GUY'S HOSPITAL

Two factors have elevated the adrenal gland to its present day importance in medicine. One was the publication by Addison of his famous blue book, for this prompted Brown Sequard to perform experimental extirpation of the gland for the first time and to study the characteristic manner in which death inevitably followed. The other factor is the renaissance of endocrinology which has taken place in recent years.

Sufficient scientific fact now invests our knowledge of the relations of this gland to the maintenance of life to enable a discussion of its relation also to sudden death from natural causes to be effected without recourse to vague theory. The conditions of sudden death however give the problem a distinctly forensic flavour and tend to limit the experience to those engaged in this work. Even here the figures are not impressive—it has been my experience to examine such cases at the rate of 1 in every 500 post-mortem examinations of subjects of sudden death from all causes including injuries.

Nevertheless the morbid anatomy of these glands with strict relation to sudden and unexpected death is a subject remarkably well defined. The figures are small but the limitation in disease processes is close. There are few morbid processes which result in the rapid destruction of the essential cortical element of both glands more or less simultaneously and these are the conditions of sudden death.

Development

In order properly to appreciate the effects of disease of the adrenal glands it is necessary to summarise certain of the facts known about their developmental anatomy and physiology.

Mammals alone possess the permanent enveloping relation of the cortex to the medulla seen in man (Fig 1) although the presence of the essential cortical tissues is universal as a distinct organ in the whole range of amniota—mammals, birds, and reptiles—and as a homologue the interrenal tissue in all anamniota as low as hags and lampreys. The arrangement in layers of this cortical element varies but its essential characters are constant.

In addition to this characteristic cellular cortex there is developed in mammals a third element a layer of cells deep to the true cortex and apparently concerned solely with the development of masculine character (Fig 1). Now at birth the weight of the adrenal gland is as much as a quarter that of the corresponding kidney; it becomes approximately a thirtieth of the weight of the kidney in adult life. This relatively large organ consists of a thin lamina of true cortex a wide zone of this third element the androgenic "masculinising" tissue and a small medulla. Immediately after birth there occurs a degeneration of the entire androgenic zone accompanied by an intense hyperemia. This may indeed prove the cause of a fatal catastrophe destructive hemorrhage taking place as a complication of

this intense hyperemic state. Reorganisation of the remains of this androgenic tissue normally takes place during the first year and thereafter the element exists only as a thin lamina coming into prominence on the rarest occasions as a malignant masculinising tumour of the cortex of one gland.

It is clear that except for the one short post-natal period during which the androgenic zone is under

FIG 1.—The normal histology of the gland. B, the capsule; A and C the adult cortex. The fetal cortex—the androgenic zone—is the pigmented layer separating B from the medulla A.

going its hyperemic involution, there is no period of life at which this tissue has any part to play in the causation of sudden death. It is entirely androgenic displaying an activity confined to sexual development.

During the development of the true cortex a free vascular circulation develops, the arterial tree ramifying in the capsule of the glands and sending from this plexus numerous capillaries which penetrate into the medulla to open out into sinuses from which venous drainage takes place. The significance of this rather unusual distribution of vessels lies in the predisposition to the impaction of arterial emboli, perhaps particularly emboli of malignant cells, and therefore to the development of secondary lesions. The matter will be discussed more fully in dealing with the morbid anatomy of the glands.

So far as the preservation of life is concerned attention may be directed solely to the cortex for that this is the essential element in the gland has been proved beyond all conceivable doubt by experimental extirpation. As to how much of one remaining cortex is required to stave off signs of deprivation experimental opinion varies. Excision of one gland and either cauterisation (Crowe and Wislocki 1914; Biedl 1910) or desiccation (Pende 1923; Stewart and Rogoff 1929) of the remaining medulla shows survival to be possible provided that from one-fourth (Bornstein and Gremels 1925) to one-eleventh (Langlois 1898) of the remaining cortex also survives intact. Administration of extracts of the cortex to adrenalectomised animals, doomed otherwise to die, retains for them conditions of physiological health which can be maintained almost indefinitely.

Relatively little attention has ever been paid to the question whether the adrenal cortex can regenerate sufficiently and with a rapidity necessary to prevent the development of insufficiency; any process resembling regeneration is seen so rarely in coming

with disease of the organ itself. In the most careful survey yet made MacKay and MacKay (1932) show that hyperplasia of the cortex of one gland does occur after operative excision of the other, but that it is an inactive process, except perhaps in the rat, takes nearly three months to develop, and requires the most encouraging conditions—conditions which

do not hold when disease is present. As a natural process, therefore, it need not occupy further attention. In so far as it concerns rapid destruction of the glands, regeneration is far too slow and uncertain to play any part in staving off insufficiency.

One further matter requires consideration. Accessory cortical tissue, occurring with some frequency in most animals, has been remarked upon with particular prominence in those of greatest bulk, including man, but it remains that accessory masses of true cortex—not androgenic—are uncommon, and when present never large enough to play any appreciable part in preventing fatal deprivation in the event of total destruction of both glands. My own

biochemical and attended by functional disorder rather than by any structural change visible to the eye. Even in the gland itself there are but few morbid processes to be found with any frequency under these conditions, three are commonly seen otherwise, and it is to these three that I wish to give attention. They are hæmorrhagic necrosis or hæmorrhagic infarction, acute caseative tuberculosis, and rapid metastatic growth invasion of the gland.

HÆMORRHAGIC NECROSIS OR INFARCTION

The adrenal glands are the site of hæmorrhage, often extensive, at two periods during life.

Neonatal type—A tendency to hæmorrhage first occurs during the hours and days immediately following birth (Levinson 1935), and as already explained, this is a misadventure which complicates the intense hyperæmia accompanying physiological involution of the androgenic (fœtal) cortex. It may occur irrespective of the nature or rapidity of delivery, but appears to be rather more frequent after difficult, precipitate, or forceps deliveries. It is properly attributed, under these conditions, to the added venous engorgement natural to such occasions, and is the more likely to provoke hæmorrhage in that it develops rapidly. Krause (1927) draws attention to the effects also of traction on the hilum of the gland, and of contraction of the musculature of the suprarenal veins which may follow traction, both increasing venous engorgement and adding to the already serious strain on the sinusoidal and capillary walls. As Lundau (1912) has, however, quite rightly pointed out, the process is primarily a physiological one, and not due to any variety of birth trauma alone. It may develop in the most carefully delivered Cæsarean sections. Both under these conditions and also under those responsible for hæmorrhage in later years, the extravasation of blood may break out through the capsule of the gland into the surrounding connective tissues, accentuating the shock like

FIG 2—Hæmorrhagic infarction of the adrenal gland and the kidney in a new born infant

in most animals, has been remarked upon with particular prominence in those of greatest bulk, including man, but it remains that accessory masses of true cortex—not androgenic—are uncommon, and when present never large enough to play any appreciable part in preventing fatal deprivation in the event of total destruction of both glands. My own records of the last 2500 cases contain descriptions of two examples, one of which was a complete heterotopia of the cortical element of that side. The irregular cortical "hyperplasias" of advanced years are of course of no functional significance in this respect.

Pathological Anatomy

Pathological changes in the body after death from acute insufficiency of the cortex are, for practical purposes, limited to those by which the gland itself is destroyed. It is true that dilatation of the heart, congestion of the lungs or pueraria or other organs and the presence of bile in the gastric contents have been noted in addition, and even credited with some significance in relation to these deaths, but these are general findings and all too common to merit any such distinction. The systemic reflections of cortical insufficiency are almost entirely

FIG 3—Acute hæmorrhagic necrosis of both adrenal glands in a girl aged 10 months following streptococcal septicæmia after pneumonia

character of the collapse which follows. The symptoms are often remarked to be identical with those of an acute upper abdominal crisis.

There is too another complication which is not perhaps so remarkable as it is often overlooked. Thrombosis of the adrenal veins often accompanies the effusion of blood into the substance of the gland. The vein is after all in close communication with sinusoids in which thrombosis has already occurred; it is a short vein half buried in the substance of a gland swollen and tense as the result of its distension by blood, and therefore most likely to become compressed adding stasis to the factors already encouraging thrombosis.

The process of thrombosis may also extend to involve the renal vein especially on the left side where the suprarenal and renal veins unite before entering the inferior vena cava. An example of this occurred under the following circumstances—

A primigravida of 35 had a normal pregnancy interrupted only at the thirty-seventh week by an attempted external version. The procedure was unsuccessful and at term delivery by a breech presentation took place being rendered additionally difficult by reason of extended legs and demanding final extraction under anaesthesia. At birth the child was alive though pale and rather shocked. It lived for 9 hours without causing alarm though it remained pale and cold. It collapsed quite suddenly without either convulsions or cyanosis about 9½ hours after delivery.

Post mortem there were no abnormalities beyond those shown in the adrenal gland and kidney (Fig. 2). Each side was affected similarly and thrombosis of both adrenal and renal veins was to be demonstrated microscopically.

A further specimen of the condition is shown in the Royal College of Surgeons museum (Spec. No. 9294.1) the presentation in this case being a vertex; there are no records of the other points of interest.

Purpuric type.—A second form of haemorrhagic necrosis also frequently attended by thrombosis of the attendant veins occurs at later periods of life when the androgenic zone hyperminia has subsided and takes place from entirely different causes unconnected with any physiological process. As a consequence of the development of a purpuric (haemorrhagic) tendency of whatever cause but more particularly following septicæmia—especially streptococcal—meningitis pneumonia and diphtheria the most extensive primary haemorrhages may occur into the substance of the adrenal gland of either one or more usually both sides disrupting its substance entirely and frequently distending the capsule to extraordinary proportions. When the process is symmetrical both cortices are destroyed with the greatest rapidity and acute adrenal insufficiency quickly develops. The condition is well illustrated by the following case.

A girl of 10 months and without previous illnesses developed a slight cough and became a little feverish, her temperature rose to 101° F. For nearly a week the condition was more or less stationary, then without apparent reason the child became most apathetic, lost appetite and within 8 hours vomited. Convulsive fits

FIG. 4—Acute tuberculosis of the adrenal gland in a man aged

developed 2 hours later and continued intermittently for another 10 hours. Vomiting was repeated during this period. After 20 hours there appeared some respiratory embarrassment and coma developed. The child died suddenly in its mother's arms after 21 hours.

Post mortem there was a well-developed acute haemorrhagic pneumonia of streptococcal type with minute friable vegetations on the mitral valve cusps indicating the spread of infection into the blood stream, and bilateral haemorrhagic necrosis of the adrenals (Fig. 3). Moderate distension only was present but no intact cortical element was seen with the naked eye. Microscopical examination of the adrenal veins showed that thrombosis was not developed.

Scheidegger (1933) has described—in a similar case in a boy of 6½ years who died after massive bilateral adrenal haemorrhage—had developed in company with streptococcal meningitis—actual perforation of the capillaries by organisms morphologically identical with those seen in the meninges. The condition is also shown in the R.C.S. museum (Spec. No. 500.2) from a nurse at work in a base hospital in France in 1917.

In this case the infection was meningococcal, lasted 24 hours in all and was terminated by the development of a coarse purpuric eruption throughout the mucous membranes and skin. The adrenal glands were both disrupted by massive haemorrhages and tinged with

FIG 5 —Massive invasion of the adrenal gland by metastatic carcinoma arising from the stomach in a man aged 55

from those just described in connexion with streptococcal pneumonia and septicaemia. Examination of smears from the spleen showed numerous Gram negative diplococci (meningococci), the case was also one of septicaemia.

In severe burns the same pathological process is seen with some frequency, especially in medico legal work. Particularly when extensive, haemorrhagic necrosis of the adrenal glands may develop with fatal results, in spite of the absence of infection. I have records of cases developing as soon as four hours and as late as seven days after injury. Thrombosis is again fairly frequent. This lesion develops as a result of the combined capillary paralysis and increased capillary permeability taking place during the period of shock following burns. It is to be distinguished from the shock like crisis accompanying destruction of the adrenal cortex, in which there is no increase in the permeability of the capillaries and no increase in the fluid content of the tissue spaces, in fact there is a progressive dehydration of the tissues. The matter will be referred to again later.

Cystic haematomata may also develop either under conditions in which the capsule bursts and extravasation of clot occurs, or after repeated smaller haemorrhages none of which is sufficiently extensive to cause death. One gland alone may be involved. Spec. No. 19121 in the R.C.S. museum illustrates this very well.

A woman, aged 44, was in good general health but suffered from occasional pain in the left loin. Five years previously an operation had been performed for a large retroperitoneal haematocoele, lying in the region of the left kidney and 'causing intestinal obstruction'. The cavity, evacuated of its blood clot, was marsupialised to the abdominal wall and packed with gauze. None of the cyst wall was removed, recovery was uneventful. The second haemorrhage was heralded by 12 hours' vomiting, and operation revealed the condition shown. The relation between the first and second haematomata was not made clear.

ACUTE CASEOUS TUBERCULOSIS

In the large majority of cases of adrenal tuberculosis the disease, being secondary, pursues an insidious course and is attended by limiting fibrosis and calcification. Addisonian changes have usually become well developed before death takes place. Tuberculosis of the glands is relatively common, accounting for at least some 70 per cent (Guttman 1930) of cases of Addison's disease, but rapid destruction of the glands on both sides likely to cause acute cortical insufficiency is uncommon. As with growth, arterial embolism is almost certainly responsible for initiation of the disease, rapid caseous necrosis, and often bulky proliferative thickening by soft granulations bringing about a very considerable enlargement of the affected gland. The following case is a good example.

A metal worker, aged 22, arrived home on a game of football complaining of abdominal pain and nausea. He had received no injury during the course of the match. Vomiting occurred within half an hour of his arrival and was repeated about 1½ hours later. Shortly after this his wife noted twitching of the muscles and of the hands, and before assistance could be summoned he had collapsed in a major convulsive fit, intense cyanosis and marked respiratory embarrassment were present, and death took place a few minutes later. The total of definite illness was less than 3 hours.

Post mortem there was both primary and secondary apical disease of the right lung, both however progressing favourably, and massive soft caseous necrosis of both adrenals (Fig 4). There was no pigmentation of the skin or mucous membranes, and no evident loss of weight. This was confirmed by the wife who described her husband as having had no illness until the day of his death.

It is especially true of the adrenal gland that with but little primary pulmonary or mesenteric disease there may be the most gross destruction by secondary proliferative and caseous disease (Elsässer 1922). When this is developed rapidly signs and symptoms of acute insufficiency may appear, and as in this case prove quickly fatal. It is of course probable that a minimum of reserve cortex was present in some days or possibly weeks before death suddenly took place, the subject is on the brink of a catastrophe without having knowledge of the fact. The frequency with which exercise, shock, or external variations in temperature cause a precipitation of fatal attack is well known, and will be discussed later.

INVASION BY METASTATIC GROWTH

Although primary malignant growths of the cortex and the medulla of the gland may result in complete destruction of the cortex of one or both, that of the other gland is rarely if ever affected, and

deprivation of both cortices does not occur sudden death from acute insufficiency is not seen in company with primary malignant growth. Metastatic growth invasion is however a process more likely to result in the destruction of both glands since it is so commonly bilateral. This form occurred in a farm labourer who dropped dead in a field while stoning furrows.

He was aged 55 and, so far as was known, had not had any illness for at least 25 years and had not complained in any way up to the day of his death. He dropped dead whilst moving slowly along a plough furrow with several companions, removing stones.

Post mortem he was in a condition of perfect health as regards the heart and vasculature but bore a small ulcerative carcinoma of the body of the stomach with several glandular infiltrations in the porta hepatis, and adrenal glands having the appearance shown in Fig. 5. There is complete destruction of both cortices and in the absence of any other cause of death the primary tumour being small, and other organs being healthy acute adrenal insufficiency was held to be responsible.

Any organ may give rise to metastases in the adrenal glands but some appear to do so with striking frequency. Willis (1933) describes deposits in 27 out of 323 consecutive cases of carcinoma growth irrespective of the site of origin and remarks upon the frequency of deposit from primary tumours of the lungs and breast and from melanomata. In over a half of these 23 the deposits were bilateral.

It is striking how far the cortex may resist destruction remaining as a thin lamina stretched out over the growth mass. This fact added to the infrequency of large bilateral deposits is a reasonable explanation of the rarity of deaths clearly from acute adrenal insufficiency in a condition as frequently seen as metastatic deposit in both adrenal glands. Willis, although not interested in the symptomatology of his cases, notes the occurrence of asthenia and vomiting as terminal symptoms of cases showing adrenal deposits at autopsy but fails to denote their relation to adrenal insufficiency.

Now something of the vascular anatomy of the gland has already been said, with particular reference to the formation of metastases. Those penetrating cortical arterioles and capillaries running vertically down through the cortex to the medulla are most likely to afford embolic sites for growth and it is surprising therefore to find that the majority of these deposits are situated first in the medulla. There can be no doubt that the arterioles and the capillaries of the cortex are unusually wide and that growth emboli may for this reason make their way successfully to the medulla. Emboli have been observed in otherwise normal glands by Adams (1923) and by Robinson (1928) and arterial embolism is undoubtedly the route by which these growths take origin. They may occur primarily in the cortex or primarily in the medulla or in both together (see R.C.S. museum Spec. No. 2112-3 from penis). On rarer occasions growth may also infiltrate direct from contiguous structures or through the lymphatics (see R.C.S. museum Spec. No. 2044-1 lymphosarcoma).

Dosquet (1921) has suggested that the high frequency of adrenal metastases and cerebral metastases in lung cancer illustrates the susceptibility to growth deposit both ectodermal nervous tissues being embedded in a matrix rich in lipoids.

Pathological Physiology

No description of the morbid anatomy of the changes in the adrenal glands in relation to sudden

death would be complete without a proper analysis of the exact sequence of events that leads to death.

A close parallel exists between the symptoms and signs consequent upon experimental extirpation of the gland and those following deprivation from natural causes.

Under experimental conditions in dogs (Banting and Gairns 1928) surviving less than 50 hours for instance the most striking changes are as follows (Fig. 6).

(a) An initial period of surgical shock (absent under natural conditions):

Weakness
Loss of appetite
Vomiting
Convulsions and
Respiratory paralysis and these are accompanied by

(b) Oliguria or complete anuria, reduced temperature, oxygen consumption and body weight. The basal metabolic rate falls by as much as 25 per cent. Changes in the blood chemistry.

The onset of these changes is insidious the subject becoming apathetic and slow weak in the hind legs then lying prostrate refusing food and often vomiting. Muscular twitchings and then frank convulsions develop respirations becoming slow and laboured and eventually ceasing though the pulse may still continue.

In the case of bilateral haemorrhagic necrosis already described these features developed with remarkable faithfulness. This infant of 10 months in turn showed loss of appetite and apathy lay prostrate and then vomited developed fits went into coma breathing with great clutching breaths then dying in its mother's arms quite unexpectedly.

Adverse conditions may precipitate these changes as for instance in the case of acute caseous tuberculosis.

FIG. 6.—The physiological changes after adrenalectomy in dogs.

described in which death was precipitated by unusually vigorous exercise—playing football. In older persons exertion may be quite mild as with the case of growth infiltration in a man who was doing, no more than bending to pick up stones from a furrow and cast them aside. Extremes of temperature may cause failure in the same way. The mechanism of this will be discussed below in connexion with the changes in blood chemistry.

BLOOD CHEMISTRY

It is in the examination of changes in the chemistry of the blood that the causes of death become apparent

(Fig 7) They are related principally to alterations in hepatic and renal function consequent upon deprivation of the essential cortical hormone. Those changes consequent upon diminution of hepatic function are reflected in a rise in the cholesterol and a fall in blood sugar, this latter may be so pronounced as to reach convulsive levels (Porges 1910), and at the same time there occurs a remarkable diminution of both liver and muscle glycogen, restoration failing

FIG 7—Changes in the blood chemistry after adrenalectomy

to take place after exercise. It is clear that the cortical hormone is essential either for the normal synthesis of glycogen by muscle, or for the maintenance of the normal balance between blood sugar and tissue glycogen.

Diminution of kidney function, related clearly to dysfunction of both glomerular and tubular elements, is reflected in a sharp rise in blood urea and other non proteinous nitrogen constituents of the blood, the urinary output being decreased.

The blood volume is reduced, together with the levels of both sodium and chloride, the urinary output of these substances vastly exceeding the intake over any period after the second day (Loeb 1923).

There is no deviation of fluid into the tissues, which indeed become dehydrated, and no passage of fluid into the red corpuscles, these becoming increased in number as the blood concentrates.

Sodium diminishes by as much as 15 per cent, on the other hand potassium values increase by as much as 12 per cent and magnesium by as much as 23 per cent effectively maintaining the falling osmotic pressure (Baumann and Kurland 1923). There can be no doubt that this unbalance of cations alone provides reasonable cause for the variations in muscle tone and movement observed.

In Fig 6 it will be noticed that the chloride loss is relatively less than that of sodium. This results, of course, in a decrease in bicarbonate and a disturbance in the acid base equilibrium, the pH falling.

Now other acute pathological conditions like diabetic acidosis and high intestinal obstruction, are also attended by much the same loss of inorganic base. They too are remarkable for their resemblance to the conditions of shock just as is acute cortical insufficiency and they too can be relieved by the restoration of sodium chloride. Immediate relief follows adjustment of the electrolyte balance (Soddu 1923). It must of course be remarked that the

condition is distinct from that of "surgical shock" it is rather an intolerance to the various influences that may cause shock. In some respects the conditions are analogous to those of hypocalcaemia after deprivation of parathyroid, and in this respect it would not be unreasonable to attribute to the adrenal cortex the control of sodium.

Conclusion

Although the loss of sodium and its attendant imbalance of electrolytes are the most striking of the processes developing in acute adrenal insufficiency, the clinical features are not adequately explained by this succession of changes alone. It is clear that both hypoglycaemia and dehydration have their parts to play, their importance in the mechanism of death cannot be ignored.

Each of these three biochemical anomalies developed in relation to cortical insufficiency has its experimental champion, Loeb supporting the changes in sodium metabolism, Britton emphasising the undeniable importance of hypoglycaemia, and Swingle and Pfiffner investing the loss of tissue fluid and plasma volume with chief responsibility. Each has claims which are irrefutable, and it is abundantly clear that all three collectively, rather than one individually, are to be held responsible for death.

I wish to express my gratitude to Dr A. D. Cowburn, Dr P. B. Skeels, and Dr L. F. Beccle, coroners respectively for South London, Metropolitan Essex, and South Essex, to whom I am indebted for certain of the specimens shown.

ROYAL LONDON OPHTHALMIC HOSPITAL—The first full year's workings at the enlarged Moorfields Hospital show that annual expenditure was nearly £50,000—an increase of over £5500. More cases were treated than ever before, a total of 66,877 being reached. Building operations have cost £181,000 and supporters are appealed to for special donations to pay off the debt.

ROYAL WEST SUSSEX HOSPITAL, CHICHESTER. The Bishop of Chichester presided on March 24th at the annual meeting of the governors of this hospital. The financial report showed an excess of expenditure over income of £211 but the figure would have been but for a legacy of £2000. Subscriptions amount only to £1495 which was less than 10 per cent of the expenditure. It was stated that an economy committee set up last year had decided that the institution economically administered and that it would not be justifiable to close down a number of beds, considering the small sum involved. The West Sussex Associated Hospital Contributory Fund had contributed £4453 to the hospital.

DIPHThERITIC MYOCARDITIS

AN ELECTROCARDIOGRAPHIC STUDY

By NORMAN D. BEGG, M.D. Aberd. D.P.H.

MEDICAL SUPERINTENDENT TO THE DOROUGH INFECTION HOSPITALS, SOUTHEND-ON-SEA

COINCIDENT with the decline in laryngeal involvement practically all the serious manifestations of diphtheria have come to be associated with the so-called faucial forms of the disease. Here the diphtheria bacillus remaining *in situ* produces a variable amount of soluble exotoxin which has a primary affinity for heart muscle and nerve tissue. Death in diphtheria results much more commonly from cardiovascular involvement than from purely paralytic phenomena and it is towards the heart complications of diphtheria that attention will be directed in this paper.

The electrocardiographic approach to this problem is not a new one. American and continental writers in particular having described the gross conductive lesions of diphtheria and correlated them with degenerative changes in the bundle of His revealed post mortem passed on to study the steps in the development of minor disorders of cardiac function which had not previously been recognised. In this way serial electrocardiograms have come to occupy a position of some importance in prognosis although almost every investigator admits that occasionally they fail to explain the whole mechanism of circulatory collapse in diphtheria. Nor in the face of certain fundamental facts is it reasonable to expect them to do so. An electrocardiogram is merely a record of the changing electrical activity within heart muscle and affords no direct evidence of structural damage—although this latter may be inferred in many cases with a considerable degree of accuracy. Moreover an electrocardiogram cannot reveal changes occurring outside the heart muscle. Thus in cardiovascular failure which is primarily peripheral in origin a normal electrocardiogram may be expected even when death is imminent. But peripheral failure by itself is a rare event in diphtheria—in the vast majority of cases the cardiac mechanism is equally involved. Hence the importance of obtaining precise information on the state of at least part of the cardiovascular system need not be emphasised.

Scope of the Investigation

The present series comprised 100 cases of severe faucial diphtheria which were subjected to electrocardiographic investigation. In order to avoid moving severely ill cases four of the diphtheria wards were wired to the electrocardiographic department. A standard Cambridge instrument was used throughout and records were obtained by the falling plate method. The first electrocardiogram was taken immediately after admission thereafter records were obtained daily or at intervals of a few days during the first three weeks and subsequently at longer intervals until convalescence was established. It was hoped from such an investigation to obtain information on the following points: (1) the frequency of various heart changes in diphtheria as revealed by electrocardiography; (2) the prognostic significance of these changes; and (3) the persistence or otherwise of diphtheritic heart lesions.

Before proceeding to study these cases in detail certain generalisations may be permissible. In the

first place direct involvement of part or whole of the cardiovascular system occurs almost invariably within the first three weeks of an attack of diphtheria although of course lesions appearing in this stage may persist for many weeks. Secondly circulatory failure in diphtheria appears in two forms. These were distinguished by Schwentker and Noel (1929) on a purely pathological basis into an early and a late type.

Early circulatory failure appears within the first few days of disease and represents the sum of toxic effects on all organs. The principal clinical manifestations are a fall in blood pressure a small rapid pulse extreme pallor cyanosis and coldness of the extremities—a physical state more commonly associated with conditions of shock than cardiac failure. Carbohydrate metabolism is invariably deranged and there is an abnormal body response to the intravenous injection of dextrose in the direction of higher blood sugar findings. Electrocardiographic evidence of myocarditis may or may not be present but is rarely so pronounced as to indicate impending death—an event which frequently does ensue.

Late circulatory failure appears usually between the third and fourteenth day of the disease. Evidence of peripheral failure may be present but the outstanding feature is clinical and electrocardiographic evidence of damage to heart muscle or to the specialised tissue of the conducting system. Death is also a common event in late circulatory failure but almost any degree of myocardial damage may be recoverable in individual cases and on the whole, the outlook is relatively better than in early circulatory failure.

Results

The average day of death in this series from circulatory failure early or late was the tenth day of disease and the latest day recorded was the nineteenth day of disease. Two deaths from broncho-pneumonia and diaphragmatic paralysis were excluded. A further study of fatal cases reveals the fact that in 3 cases only could the associated circulatory failure be described as the early type and two of these showed some electrocardiographic evidence of myocarditis. In contrast deaths typical of late circulatory failure numbered 23 and in each case there was electrocardiographic evidence of myocardial involvement with or without the addition of a frank conductive lesion.

It is possible to divide the 100 subjects of this investigation into three groups consisting of (a) those showing no significant abnormality (b) those showing evidence of myocarditis without a gross conductive lesion and (c) those showing an associated conductive lesion. The results of such a classification are summarised in the Table.

It will be seen that 84 per cent of cases developed some electrocardiographic abnormality as a result of diphtheria and that in no less than 27 per cent of all cases this abnormality took the form of a conductive lesion the mortality in the latter group being more than twice that of the group showing no predilection for the conducting system.

A description of the chief abnormalities revealed in the three groups is given below and the significance of each is discussed. It is necessary to emphasise the fact that lesions merge into each other and that combinations of two or more lesions are by no means uncommon. Hence the classification used is only one of convenience in an attempt to study the salient abnormality of individual cases.

TABLE SHOWING CASE FATALITY IN VARIOUS GROUPS DETERMINED BY ELECTROCARDIOGRAPHIC CHANGES

—	No significant abnor- mality	Myocarditis							Total
		No demonstrable conductive lesion				Demonstrable conductive lesion			
		Slurred Q R S	Low voltage	Changes in T	Paroxys- mal tachy- cardia	Complete heart block	Bundle branch block	Intra- ventricular block	
Cases	16	8	6	35	8	12	6	9	100
Deaths	1	1	0	4	8	8	4	2	28
Case fatality per cent	6.2	12.5	0	11.4	100.0	66.7	66.7	22.2	28.0
Total mortality per cent	6.2	22.8				51.9			28.0

APPARENTLY NORMAL GROUP

As a normal electrocardiogram varies within tolerably wide limits, no significance has been attached to inversion of the T wave in lead III, or to a low, notched QRS complex in lead III. When the tracing is otherwise normal these variations appear constantly in successive records and remain uninfluenced by the disease. Alstead (1932) does not regard evidence of electrical axis deviation of the heart as significant. In his experience this change, unless it appeared in serial records during the course of the disease, was not associated with an abnormal heart clinically. I am in complete agreement with this observation and 5 such cases are included here. The remainder, showing physiological electrocardiograms throughout, included one in which death occurred from early circulatory failure. Electrocardiograms taken from this case on the fourth, seventh, and ninth day revealed no abnormality and clinical examination of the heart failed equally to anticipate the sudden circulatory collapse that took place on the tenth day of the disease.

MYOCARDITIS GROUP

The abnormalities in this group are associated with the ventricular portion of the tracing. Evidence of a minor prolongation of conduction time may also be present but the main characteristic is not a gross lesion of the conductive system.

QRS complex—This represents the first stage of ventricular activity. Each deflection of a normal QRS complex is recorded as two uninterrupted evenly shaded straight lines, which converge to a sharp point. Pronounced shading at any point is abnormal and results in a slurred QRS. In diphtheria slurring takes place on the down stroke of the R wave and in extreme cases results in a deep curved S wave (Fig 1 A)—a direct precursor of T wave changes. By itself it indicates a moderate degree of myocarditis which is unlikely to cause death in the absence of peripheral failure. However, of 5 cases exhibiting this abnormality, 1 died of early circulatory failure on the seventh day of disease.

T wave changes—The T wave is the final evidence of ven-

tricular activity. Normally it is upright and has an amplitude which should not be less than 0.15 millivolt. In diphtheritic myocarditis the T wave may be depressed, diphasic, iso electric, or inverted. A typical example is shown in Fig 1 B. T wave changes of any degree commonly indicate more severe myocarditis. In diphtheria, however, the outlook is reasonably good, since of 35 cases showing this abnormality only 4 died, death in 1 case being primarily due to broncho pneumonia.

Low voltage—Normally the R wave amplitude does not fall below 0.6 millivolt except in lead III or less commonly in lead I. Considerably lower voltage in all three leads of an electrocardiogram were occasionally recorded in this series. By itself this does not appear to have serious prognostic significance but when T wave changes are associated with low amplitudes (Fig 1 C) severe myocarditis may be assumed.

Disturbances of the pacemaker—The heart beat normally originates in the sinus node. Occasionally through nervous or other disturbances the pacemaker may not function properly and the beat may originate in other parts of the heart. For example, where the source of heart rhythm is abnormally situated some where in the auricular ventricular nodal tissue a record such as shown in Fig 2 is obtained. Extrasystole on the other hand arise independently of the normal heart rhythm and always from a focus outside the

FIG 1—DEGREES OF MYOCARDITIS

- A—Slurring of the R wave and deep curved S in leads II and III and a biphasic T wave in lead I. Moderate myocarditis.
 B—The ascending limb of the R wave in lead II is splintered, there is slight intraventricular delay, the T wave is inverted in each lead. More severe myocarditis.
 C—The maximum voltage of the R wave in any lead is 0.5 millivolt. The T wave is inverted in leads I and II. Severe myocardial damage.

sino auricular node. In diphtheria they are usually ventricular in origin and in common with disturbances of the pacemaker do not appear to indicate a myo-

carditis of any degree if the record is otherwise normal.

FIG. 2.—The P wave is occasionally buried in or can be seen jutting out from the QRS complex. Nodal rhythm.

carditis of any degree if the record is otherwise normal.

Tachycardias not of sinus origin are paroxysmal in character and represent a rapid and regular succession

of premature contractions which may arise in an ectopic focus in the auricle, auriculo ventricular junctional tissues or ventricle. In the present series one example of paroxysmal auricular tachycardia (Fig. 3 A) ending fatally was observed. Paroxysmal tachycardia of ventricular origin (Fig. 3 B) was seen on 7 occasions and it is significant to note that each patient died within a few days of the appearance of this abnormality.

Ventricular fibrillation is probably a fairly frequent terminal event in a dying heart muscle although Josephthal (1934) records a case of post diphtheritic ventricular fibrillation which recovered. Attempts to obtain terminal pictures in this series were uniformly unsuccessful. This must be attributed to the time lost in manipulation of plates during an exposure; it is a method of obtaining records that is ideal for ordinary purposes but poses great disadvantages when a continuous record is desired. An electrocardiogram taken within half an hour of death is shown in Fig. 7.

Coronary thrombosis.—In spite of suggestive clinical findings, such as severe precordial pain and sudden termination in heart sounds, the RS-T segment changes characteristic of coronary thrombosis were never seen in this series. Other gross lesions may obscure the electrocardiographic picture in individual

FIG. 3.—PAROXYSMAL TACHYCARDIA.

A.—The rate is rapid (180) the rhythm is regular the distinct peaked P waves identify the auricular source of the tachycardia. Paroxysmal auricular tachycardia.
B.—The rate is rapid (176) the rhythm is irregular the P waves are buried in distorted ventricular complexes. Paroxysmal ventricular tachycardia.

CONDUCTIVE LESIONS

Complete heart block.—Auriculo ventricular block may occur in three stages. The earliest manifestation is a delay in auriculo ventricular conduction time resulting in a prolongation of the P-R interval in the electrocardiogram. A further delay will lead to dropped beats at regular or irregular intervals. If conduction is still further disturbed there occurs a complete dissociation between auricles and ventricles which respectively adopt independent rhythms (Fig. 4 A). A characteristic of diphtheritic lesions of the main bundle of His is that complete auriculo ventricular dissociation appears usually without preliminary changes in the P-R interval. In this respect they differ considerably from complete heart block arising

FIG. 5.—The wide notched QRS complexes are directed upwards in lead I and downwards in lead II and III. The T wave in lead I is opposite in sign to the main initial deflection but in lead III it is in the same direction. Atypical right bundle-branch block.

from causes other than diphtheria. Marvin (1925) however unlike other observers did record a significant P-R delay before the onset of complete heart-block. Preliminary prolongation of the P-R interval was not seen in this series, the usual sequence being some abnormality in the ventricular portion of the tracing and then suddenly complete dissociation. Diphtheritic dissociation differs from other forms of complete heart block in two other respects.

In the first place it may be very transient complete heart block in one case in this series lasted only 24 hours. Secondly, it is not invariably associated with a slow ventricular rate. In some cases the ventricular rate is fast.

FIG. 4.—COMPLETE HEART BLOCK.

A.—The ventricular rate is slow (23) the auricular rate is 85. There is complete auriculo ventricular dissociation a ventricular extra-systole occurs regularly after each ventricular beat. Complete heart block with coupled beats.

B.—The ventricular rate is fast (135), the auricular rate is 100. The auricle and ventricle are beating independently and regularly. Complete heart block with fast ventricle.

cinated with a fast ventricular rate (Fig. 4 B) may be impossible to detect on ordinary clinical examination. The outlook in the presence of complete heart-block has invariably been stated to be grave. In this series it was no worse than in the presence of bundle branch

FIG 6—The QRS complex is wide (0.12 sec) notched and directed upwards in each lead, the T wave is upright. Intraventricular block.

block, a third of the cases in both categories recovered.

Bundle branch block.—Conduction of the wave of excitation may be partially or completely blocked in its passage through either the right or the left branch of the bundle of His. Typically the electrocardiographic evidences of complete block of a branch of the bundle of His consist of a wide notched R wave and a T wave opposite in sign to the main initial deflection. Less commonly the T wave in lead I or lead III may fall in the same directions as the QRS complex (Fig. 5). In this series 6 cases showed bundle branch block, the right branch of the bundle being involved only in one instance.

Intraventricular block.—Oppenheimer and Rothschild (1917) in pointing out the seriousness of bundle branch lesions in diphtheria included in their description a partial interference with one of the main bundle branches. There is some doubt whether electrocardiograms showing incomplete block do represent interference with conduction in the fine ramifications of the Purkinje network or in the ventricular muscle. Characteristically the electrocardiogram reveals a slurred or notched QRS widened beyond the normal limit of 0.1 sec and a T wave which may be upright, depressed, or inverted (Fig. 6). Of all conductive lesions in diphtheria intraventricular block appears to be the least serious. Only 2 cases showing this lesion died, and in 1 of these the case made a complete electrocardiographic and clinical recovery from the heart lesion, but succumbed later to diaphragmatic paralysis.

RECORDS IN CONVALESCENCE

Contrary to expectation electrocardiography does not yield much evidence of persistent heart damage after diphtheria. Undoubted examples of permanent lesions have been recorded but, unless one believes with Butler and Levine (1930) that diphtheria predisposes a heart to earlier sclerosis than would normally have taken place, the striking feature of the severe myocardial lesions in diphtheria is that recovery in non-fatal cases should apparently be so complete. Probably the true incidence of permanent lesions after diphtheria will not be assessed until a representative group of children are investigated periodically throughout an attack and for several years to follow. In this respect the observations recorded here are open to the same objection in that they represent only part of a picture. However, serial electrocardiograms of 57 cases who had

developed definite heart lesions in the course of diphtheria were continued until convalescence was established. On two occasions only was any evidence of significant electrocardiographic abnormality obtained. This consisted in one case of a minor degree of widening of the QRS complex following complete heart-block and in the other case low heart voltages were recorded following bundle branch block.

Summary

1 Investigation of a series of 100 cases of severe diphtheria shows that the great majority develop cardiac abnormalities within the first three weeks of the disease. In many cases the exact nature of the abnormality cannot be recognised except by the auxiliary evidence of an electrocardiogram.

2 If complete heart-block, bundle branch block or paroxysmal tachycardia appear in electrocardiograms during the course of diphtheria, the outlook as regards recovery is relatively bad.

3 In the presence of other evidence of myocardial involvement, including intraventricular block, the prognosis is reasonably favourable.

4 A normal electrocardiogram, particularly within the first few days of the disease, does not preclude the possibility of a sudden circulatory collapse, and, in this respect, clinical examination may be equally misleading. Probably at this stage of the disease an intravenous sugar tolerance curve remains the most sensitive guide to prognosis.

FIG 7—There is complete auriculo-ventricular dissociation, the ventricular complex recurs irregularly and consists of a large irregular R wave followed by an abnormal S-T phase. Complete heart block of the myocardium.

5 Except in a small proportion of convalescent lesions, recovery after diphtheritic myocarditis appears to be complete as judged by electrocardiograms taken in convalescence.

I wish to acknowledge my indebtedness to Dr E. H. Harries for the facilities afforded me in obtaining these records since I left the North Eastern Hospital and for his permission to publish this paper.

HOSPITAL AND ASSISTANT SURGEON TO THE
ABERDEEN ROYAL INFIRMARY

THE physiology of the menstrual cycle has in recent years been considerably clarified by the isolation of the ovarian hormones and the demonstration of their pharmacological actions. The present state of knowledge has however been reached mainly as a result of animal experiment. It is clear that the rational use of these hormones in therapeutics will only be possible when the part which they play in the human menstrual cycle is fully understood and the important details of optimum dosage and time of administration have been obtained by experiment in the human subject. The experiments to be described in this communication were carried out on normal women with the object of obtaining more complete information regarding the function of the corpus luteum and to determine the dose of corpus luteum hormone required to produce an effect similar to that produced by the corpus luteum itself.

It is now well recognised that treatment of castrated animals with oestrone prevents the development of the regressive changes in the genital tissues consequent upon castration. E. Allen (1932) has shown that the injection of oestrone into castrated monkeys (*Macacus rhesus*) will so far simulate the action of endogenous hormone as to produce not only growth of the uterine endometrium comparable to that seen in the normal animal about the middle of the menstrual cycle but also reddening of the sexual skin a phenomenon which occurs normally in *Macacus rhesus* in the mid-menstruum. Zuckerman and Morse (1935) have been able to produce in primates a cystic condition of the endometrium similar to that which may occur in woman and which is associated with over production of oestrone (metropathia haemorrhagica). This condition has also been produced in the human subject by prolonged treatment with oestrone (Kaufmann 1934).

CONTROL OF THE ENDOMETRIUM

So far as the early part of the menstrual cycle is concerned therefore the growth of the uterine endometrium would appear to be under the control of the ovarian oestrone. With regard to the latter part of the cycle it has for long been thought that the change in structure which the endometrium undergoes after ovulation is due to the influence of the corpus luteum. This conjecture is supported by the finding of Corner and Allen (1929) that the injection of an active extract of corpus luteum into the oestrus rabbit alters the structure of the endometrium from the oestrus state to that typical of pseudo-pregnancy. It was subsequently shown by W. M. Allen (1930) that the hormone of the corpus luteum could only produce such a change if the endometrium was first acted upon by oestrone. Later Hsaw Meyer and Ferold (1930) and Smith and Engle (1932) demonstrated the fact that the typical pre-

menstrual endometrium could be produced in castrated rhesus monkeys by treatment with oestrone followed by corpus luteum hormone. The final integration of these findings and their application to the human menstrual cycle was performed by Kaufmann (1934) who succeeded in reproducing a complete menstrual cycle associated with the typical changes in the endometrium in castrated women by injecting 250 000 mouse units of oestrone every fourth day for 15 days and following this with 21 clinical units of corpus luteum hormone daily for five days. Cessation of the injections was followed by true menstrual bleeding.

It has thus been established that the cyclical endometrial changes which precede menstruation are under endocrine control, but the cause of the phenomenon of menstruation itself remains obscure. That the hormone of the corpus luteum is not necessary for menstruation is suggested by the observation that in both monkeys (E. Allen 1927) and women (Corner 1933) haemorrhage can occur regularly from the uterus in the absence of ovulation and therefore in the absence of a corpus luteum. Further it has been shown by E. Allen (1927) that, after endometrial growth has been induced in monkeys by oestrin the subsequent cessation or diminution of the dose is followed by uterine bleeding. A similar finding has been made in the case of women by Werner and Collier (1933). The view thus gained support that normal menstruation occurs as a result of the sudden deprivation of oestrin. This hypothesis is however apparently confounded by the experiments of Engle et al. (1935) who showed that bleeding following the cessation of oestrin injections can be prevented by the administration of corpus luteum hormone and that stopping the corpus luteum treatment is followed by bleeding within 4 to 6 days. We have thus at least two possible explanations of the cause of menstrual haemorrhage: (1) that the haemorrhage occurs when the level of blood oestrons falls below that necessary to maintain the endometrium and (2) that the haemorrhage and degeneration of the endometrium result from the loss of corpus luteum hormone consequent upon degeneration of the corpus luteum.

If the former hypothesis is correct it should be possible to postpone the onset of menstruation in women by the continuous administration of oestrone. This has been tested by Zuckerman (1936) and others who find that the administration of oestrone in daily doses of 250-1000 rat units fails to prevent the onset of menstruation unless the injections are begun before the time of ovulation. This finding is explained not by a direct action of the oestrone on the endometrium but by its action in inhibiting the production of gonadotropic hormone by the hypophysis so that in the case where oestrone is administered early in the cycle ovulation fails to occur and no corpus luteum is formed. The endometrium thus remains under the unopposed influence of the exogenous oestrone and bleeding is delayed so long as the administration is continued. If however injections are begun after a corpus luteum is formed menstruation occurs at the expected time in spite of the continuous administration of oestrone. This interpretation of Zuckerman's results is supported by the observation of Hsaw Meyer (1935) that in monkeys the administration of oestrone will prevent the onset of bleeding after ovariectomy only if the operation is performed during the early part of the cycle, i.e. an active corpus luteum is present in the ovary.

As already indicated our experiments out to test the second of these

determining first if it is possible to delay the onset of menstruation by the continuous administration of corpus luteum hormone during the latter part of the menstrual cycle, and secondly if, and in what dose, a corpus luteum hormone would replace the function of the normal corpus luteum. The hormone used was Proluton (Schering Kahlbaum). The active principle in this preparation is a synthetic derivative of stigmasterol and has the same formula as that described for the natural hormone of the corpus luteum by Butenandt and Schmidt (1934), 5 mg has a potency of 20 clinical units. The preparation was tested by us to prove its activity in altering the structure of the rabbit endometrium, and in diminishing the motor activity of the uterus, and was found to possess both these properties.

It was necessary to perform a number of control observations, and accordingly the experiments will be described in three parts—

- Observations on the effect of excision of the recent corpus luteum on the menstrual rhythm
- Observations on the effect of administering corpus luteum hormone in the latter part of the menstrual cycle
- Observations on the effect of substituting exogenous hormone after surgical removal of the corpus luteum

EFFECT OF SURGICAL REMOVAL OF THE CORPUS LUTEUM

For this part of the investigation female patients requiring operation for chronic appendicitis were utilised, and only those in whom there was no evidence of any gynaecological disorder, and who could provide an accurate menstrual history, were included in the series.

Where possible the patient was observed in the ward during one menstruation and the operation was performed at a selected time in the succeeding intermenstruum. In this way ten cases were operated upon after the 15th day of the cycle counting from the first day of the previous menstruation, and at the operation the ovaries were inspected and the recent corpus luteum excised. In each

CHART 1—*Laparotomy with Excision of Corpus Luteum*

case it was examined histologically to corroborate its age. It was observed that in cases operated on near the middle of the menstrual cycle the corpus luteum was fresh and incompletely formed, whereas in two cases operated upon late in the cycle the histological appearance of the gland indicated that ovulation had occurred much later than the 15th day of the cycle. On the other hand it was never found that a case operated on shortly after the 15th day showed a degenerating gland.

The time of onset of uterine bleeding carefully noted in each case, was never longer than 48 hours after the operation, the average time of onset throughout the series being 32 hours (Fig 1).

According to Pratt (quoted by Bartelmez 1937) the effect of surgical removal of the corpus luteum in precipitating the onset of menstruation is not specific, and any manual manipulation of the ovary may induce premature menstruation. To determine therefore if the operation per se, or the manipulation necessary in excising the corpus luteum without actual removal of the gland, would be sufficient to precipitate menstruation, two additional sets of observations were made.

CONTROL GROUP 1—Cases selected upon the criteria already described were submitted to operation in the latter

CHART 2—*Laparotomy without Handling Ovaries*

part of the intermenstruum, and in these the pelvic viscera were not disturbed, the ovaries being as far as practicable inspected to ascertain the presence of a corpus luteum without handling them in any way. In 4 cases in this group the onset of menstruation was not accelerated and occurred at or about the expected date. In 2 cases menstruation appeared earlier than the expected time but in no case did menstruation occur as soon after operation as in the previous group (Fig 2).

The average interval between operation and menstruation was 6.1 days.

CONTROL GROUP 2—A third group of 7 cases was examined in the same way, but in these the ovaries were delivered at the wound and handled, though the corpus luteum was not removed. In 4 cases the onset of post-operative menstruation was not hastened. In Cases 19, 21, and (Fig 3) an interval of 5, 3, and 6 days respectively elapsed between the operation and the appearance of menstruation. It is interesting to note that in Cases 18 and 23 small cysts were excised from the ovaries.

Even when, therefore, the traumatism of an ovary was as great as in the cases in which the corpus luteum was removed, the occurrence of post-operative menstruation was delayed for 5, 5, and 6 days.

THE ACTION OF CORPUS LUTEUM HORMONE ON MENSTRUATION

The experiments just described have shown that excision of the corpus luteum precipitates the onset of menstruation. To test the theory that menstruation is brought about by loss of the corpus luteum, an attempt was next made to delay the onset of bleeding in normally menstruating women by intramuscular injection of proluton. The investigation was carried out on patients submitted to prolonged hospitalisation on account of chronic pulmonary tuberculosis.

Patients presenting a history of regular menstruation were selected, and the interval between successive menstruations was determined over 3 or 4 months in each. Shortly before the onset of the expected menstruation intramuscular injections of proluton were begun and continued daily until menstruation started. Since it was impossible in most cases to foretell with any degree of certainty the day of onset of menstruation, the

received courses of injections of the hormone of different duration. The daily dose was varied from 20 clinical units to 40 clinical units. It will be seen from the Table that the administration of corpus luteum hormone in doses ranging from 60 clinical units over a period of 3 days to 520 clinical units over a period of 13 days did not delay

Case No.	Control duration of intermenstrual periods in days.		Daily dose of proluton (clinical units)	Injection period in days	Total dose (clinical units)	Duration of treated cycle in days.
24	28	30	40	3	80	33
25	40	38	32	40	11	440
26	28	31	31	20	3	60
27	27	40	34	20	3	60
28	20	24	30	40	6	240
29	30	28	30	20	3	60
30	34	31	31	0	3	60
31	28	20	10	40	10	400
32	3*	32	33	40	5	200
33	32	30	33	40	11	440
34	34	34	32	40	11	440
35	34	32	32	40	0	360
36	30	30	28	40	11	440
37	28	20	30	10	13	50
38	28	28	30	40	13	520

Onset of Menstruation—Spontaneous in each case

In Cases 25, 34, and 36 the intermenstrual interval lasted 43, 44 and 38 days that is 10, 6 and 7 longer than the average duration of three normal cycles but we have observed even greater variations to occur spontaneously in the menstrual rhythm

CHART 3—Laparotomy with Manipulation of Ovaries

normal women so that no importance can be placed on this finding. Of great significance is the fact that in each case of this series menstruation occurred spontaneously during the course of the injections.

It is apparent from these experiments that the intramuscular injection of proluton in doses of the order of 500 clinical units will not delay the onset of menstruation and since excision of the corpus luteum is constantly followed by menstruation within most 48 hours one may fairly conclude either that the onset of natural menstruation is not determined by degeneration of the corpus luteum but by some other factor or that the substance injected was capable of stimulating the action of the natural hormone. It was necessary therefore to determine whether far injection of proluton would replace the action of the corpus luteum after it had been excised.

EFFECT OF ADMINISTERING PROLUTON BEFORE AND AFTER SURGICAL REMOVAL OF THE CORPUS LUTEUM

Excision of the corpus luteum was carried out in seven patients coming to operation for chronic abdominal disease.

The cases were operated upon about the middle of the menstrual cycle and injections of proluton in daily doses of 40 clinical units were begun at various times before operation and continued after the operation until menstruation occurred. The maximum pre-operative injection

CHART 4—Excision of Corpus Luteum and Injection of Hormone

period was 6 days, giving a total dose of 240 clinical units. As in the previous cases the corpus luteum was examined histologically to ascertain its approximate age. In this series, two cases menstruated within 48 hours, two in 72 hours, two in 4 days and in one menstruation was delayed for 6 days, after which it occurred spontaneously. As will be seen from Fig. 4 the time after operation at which bleeding occurred bore no relation to the dose of proluton administered before the operation.

Although the interval between operation and menstruation was longer than the interval in the first series, where the corpus luteum was excised and no proluton given, hemorrhage occurred spontaneously in every case.

DISCUSSION

The foregoing observations show that excision of the corpus luteum is constantly followed within 48 hours by menstruation and it is clear from the control experiments that this result is not due to trauma of the ovaries. At first sight this finding seems to support the theory that the onset of menstruation is caused solely by degeneration of the corpus luteum and consequent loss of its secretion, a view supported by the fact that the intramuscular injection of hormone before and after excision of the corpus luteum produced a variable but significant delay in the onset of bleeding. It was however not found possible to delay indefinitely the onset of menstruation artificially induced nor was there any constant relation between the amount of the hormone injected and the delay produced. It is of course well recognised that the absorption from the tissues of fat soluble drugs injected in oily solution is slow and uncertain a fact which may serve to explain the relative inefficiency of replacement therapy. If this explanation is correct, it is a significant point which all those who employ corpus luteum hormone for therapeutic purposes should keep in mind. On the other hand, the fact that it was found impossible to delay in any way the onset of natural menstruation by the injection of doses of the hormone much larger than those which were effective in delaying menstruation induced artificially raises the important question as to whether the onset of normal

menstruation is determined solely by degeneration of the corpus luteum. Indeed our observations suggest the possibility that naturally recurring menstruation is brought about by some factor other than or additional to degeneration of the corpus luteum, and consequent lowering of the level of luteal hormone in the blood.

SUMMARY

1 Excision of the recent corpus luteum is followed within a period of 1·3 days (32 hours) by menstrual bleeding having all the characters of normal menstruation.

2 Surgical manipulation of the ovaries, leaving the corpus luteum intact, is not followed by menstruation until a much longer period, average 6·1 days.

3 Injection of proluton, a substance having the actions of the corpus luteum hormone, before and after excision of the corpus luteum may cause a delay of 3-6 days in the onset of menstruation.

4 The injection of proluton in doses up to 520 clinical units into normal women during the latter part of the menstrual cycle does not delay the onset of menstruation. It is possible, therefore, that the onset of normal menstruation is not determined solely by degeneration of the corpus luteum.

We desire to express our thanks to Prof David Campbell for valuable advice and criticism in the performance of this work, and to Dr Harry Rae, the medical officer of health, for placing the facilities of Woodend Hospital at our disposal.

THE VALUE OF PERSISTING WITH DRIP BLOOD TRANSFUSION IN SEVERE PROLONGED HÆMORRHAGE

By ALAN W CUBITT, B M Oxon, F R C S Eng
 SURGICAL REGISTRAR, MIDDLESEX HOSPITAL, LONDON

THE mortality from hæmorrhage is still sufficiently high to cause considerable dissatisfaction with present methods of treatment. The first aim is to stop hæmorrhage by the most direct means possible. In some cases it will be clear that surgery is the method of choice, in others it will be equally clear that surgery offers no prospect of stopping the bleeding. In another group of cases it may be very difficult to decide whether or not an operation gives the best chance of success and it may be only after careful observation of the progress of the case that the right decision can be made.

In all these circumstances the transfusion of blood may be necessary during the period of hæmorrhage. It may be given with one or more of three main objects: to make possible and safe the direct surgical intervention which may be necessary for the arrest

of hæmorrhage, to protect a patient, already dangerously exsanguinated, from the risk of further loss of blood, or to maintain life until the hæmorrhage stops. After arrest of hæmorrhage replacement of some of the blood lost may be desirable for convalescence or for other reasons.

The introduction by Marmott and Kekwick (1918 and 1936) of the continuous drip method of blood transfusion has overcome most of the technical difficulties of giving slowly and safely adequate quantities of blood over a long period. The quantity of blood required may occasionally be very large. It is above all in those cases in which the need for operation is in doubt that the method should make the right decision possible and the right treatment practicable. We can now afford to observe the progress of the patient and estimate the probability of spontaneous arrest of the hæmorrhage, the grave risk to life either of too long delay or of precipitate intervention.

Too low a hæmoglobin content of the blood may endanger life either by giving too small a margin of safety in case of increased hæmorrhage or by lowering the resistance that the patient succumbs to broncho-pneumonia or some septic complication of his condition. Where prolonged bleeding is occurring from the alimentary tract the question of nutrition becomes of vital importance. Whatever may be our opinion of the influence of diet on the continuance of hæmorrhage, it can hardly be doubted that malnutrition is an added factor of danger, that intravenous and rectal alimentation over a prolonged period is a poor substitute for the normal method. Nourishment can be given by mouth with greater confidence if blood can be supplied in quantities sufficient to keep the patient above the danger level.

This paper is written and the cases recorded in the hope of showing that when really large amounts of blood are necessary they can usually be obtained, can be safely given and that persistence and faith may be rewarded by the survival and restoration to health of patients who a few years ago would almost certainly have died of hæmorrhage.

CASE 1—A man of 42 who had been in the army had lived in Hong Kong had had intermittent attacks of obstructive jaundice for four months, sometimes accompanied by pain. The jaundice caused a trying pruritus. He had some indigestion. He had similar symptoms in 1928 and an operation in a hospital had relieved them. Details were not available but he was said to have had a cyst in the region of the pancreas. On examination he was moderately jaundiced, the urine contained bile and the stools were clay-coloured. There was a right upper paramedian scar and a large cystic swelling apparently attached to the right lobe of the liver and moving with it. It extended down to the umbilicus, it was not tender. Radionuclide showed areas of calcification at the periphery of a spherical tumour. Casoni and hydatid complement fixation tests were negative. The Wassermann reaction was negative.

The alternative diagnoses appeared to be hydatid cyst of the liver or pancreatic cyst. When first, three months earlier, operation was not advised, attacks of jaundice, however, had increased in frequency and severity and irritation was intolerable. A laparotomy was performed by Sir Alfred Webb Johnson through a midline incision above the umbilicus. The cyst was found to be pancreatic in origin, the common bile duct, duodenum and some very large veins were stretched over it and dilated. It was impossible to remove the cyst and it was therefore marsupialised. The fluid in the cyst was clear and contained diastase, lipase, tryptase, urea and chlorides. About nine days after operation he began to complain of epigastric pain and anorexia and the upper abdomen became very distended and tympanic, the pain became very severe. It

supposed that this was due to obstruction of the duodenum by the massed-up cyst and this supposition was confirmed by radiography after a small barium meal after a few days the symptoms improved but it was noted that he looked very pale and on the fourteenth day after operation he had a very large hæmatæmia followed by a large stool consisting mostly of changed blood.

The hæmoglobin percentage was estimated as 30, the patient's blood-group was 4 (Moss), the blood pressure as 85 systolic 60 diastolic. A continuous-drip blood transfusion was started. Bleeding continued for 11 days there were several hæmatæmias, but the main blood loss was by the bowel. The source of bleeding was presumed to be varices in the duodenum caused by prolonged partial obstruction of the veins stretched over the cyst. The uncertainty of the cause and site of the hæmorrhage put operation out of the question. For the first two days water only was given by mouth and saline given by rectum. After rectal alimentation was very unsatisfactory, because of the frequent large mælena stools, and as bleeding showed no sign of abating Moulengracht's diet was started. Injections of Hemoplastin and calcium gluconate were given from time to time. 11 litres of blood were given by continuous-drip blood transfusion within ten days. Some thrombophlebitis occurred and the cannula was changed into a different vein eight times, with an interval of a few hours on three occasions the longest interval being 2½ hours. During these intervals the hæmoglobin percentage of the blood fell rapidly, massive hæmelenæ continued and the transfusion had to be resumed. It was our deliberate policy not to raise the hæmoglobin percentage above 50 as long as bleeding was still going on. On the eleventh day there was no more mælena, the hæmoglobin was raised to 60 per cent and the transfusion was stopped. The hæmoglobin remained at 60 per cent for 24 hours and a further 1·42 litres of blood raised it to 65 per cent. The total quantity of blood transfused in 11 days was 13·12 litres; we think this must be a record of quantity in the time. There was no more bleeding and hæmorrhage thereafter was rapid. The discharge from the wound lessened after several injections into it of 1 in 4000 silver nitrate and 14 weeks after operation the sinus was healed and the patient a fit man. During the transfusion occasional pyrexia and thrombophlebitis were the only untoward events. Invariably while the transfusion was proceeding the patient expressed himself as feeling fine but during the intervals when the hæmoglobin was at a low level he felt very weak and ill. The blood was obtained from 24 donors; they were of Group 4 and their blood was also tested for incompatibility directly with the patient's serum. The blood of two donors were from the Red Cross Society's Transfusion Service because the blood was required urgently in the middle of the night. All the other donors were men who worked at the factory where the patient was employed. Eighty-six men were grouped in batches of sixteen or more at a time. The men and their employers were very anxious and willing to help and many of those who were found to be unsuitable were most disappointed.

CASE 2.—A man aged 35 who had had a gastro-duodenal ulcer for six years previously. He had for the last six months he had had pain after food and apparently there had been loss of weight. He was admitted with signs and symptoms of internal hæmorrhage though hæmatæmia or mælena had yet occurred. On admission: hæmoglobin, 30 per cent blood pressure 100/70; pulse rate 120. Transfusion was commenced within 1½ hours of admission and 0·8 litres of blood were given by the continuous-drip method over a period of 1½ hours with an interval of 9½ hours. When it was found that hæmorrhage was still continuing rapidly the hæmoglobin percentage was raised to 50 and laparotomy was performed 28 hours after the commencement of the transfusion. A large spurting artery of the transverse colon was found in the base of an anastomotic ulcer and was ligatured and the opening sutured. The transfusion was continued during and after operation until the hæmoglobin percentage was 70. Good recovery.

It is sometimes objected that such large quantities of blood as these are rarely obtainable. It is note

worthy that of the 37 donors bled for these two cases only four were Red Cross Society's donors. A patient's workmates are often a willing and valuable source of blood and in other cases if the onus of responsibility for finding donors is firmly put upon the relatives, sufficient blood is usually obtainable.

I wish to thank Sir Alfred Webb-Johnson and Mr E. W. Riches for permission to publish these cases and Dr F. Knights, who performed the transfusions.

CYSTICERCOSIS AS A CAUSE OF EPILEPSY IN A DIABETIC INDIAN

By R. L. HAYLAND MINCHIN, M.D. Edin. I.M.S.

PHYSICIAN TO THE GOVERNMENT GENERAL HOSPITAL,
AND ADDITIONAL PROFESSOR OF MEDICINE,
MEDICAL COLLEGE, MADRAS

No case of cysticercosis giving rise to fits in an Indian has yet been described though MacArthur (1933) has reported 22 such cases in British soldiers returning home after service in India. It is probable though of course not proved that these cases were infected with cysticerci derived from their own worm. Recent work on the development of the cysticercus stage of *Tænia saginata* (Penfold, Penfold, and Philips 1936) shows that in cattle, its normal host this cyst never lives more than nine months and then stays only in the muscles and never enters the central nervous system of the infected animal. Research is certainly required to show whether the *Cysticercus bovis* develops and dies with such regularity in other hosts and to calculate the duration of *Cysticercus cellulosa* in the infected pig and less normal hosts.

In July 1936 I saw the Hindu patient described below and requested that he should be transferred to my wards in the Government General Hospital Madras from the Mental Hospital, as the case appeared to be a combination of diabetes mellitus and idiopathic epilepsy two diseases which an extensive search in the published reports has failed to reveal as occurring simultaneously and which Joslin (1928) has been unable to discover among the 6000 hyperglycæmias he investigated. Further the combination of these two conditions would disprove the hypothesis I have advanced (Minchin 1933) that idiopathic epilepsy is associated with hyperfunction of the islets of Langerhans, and would also show that the beneficial results reported from dietetic measures to control epileptic hypoglycæmias by Thomas (1936) and the results of partial pancreatectomy described by Seale Harris (1933) and others were due to some other cause than the consequent rise of the blood sugar level.

CASE HISTORY

The patient belonged to a non-vegetarian caste and had been admitted to the Mental Hospital in November 1935. He was mentally confused and would give very little account of himself. No relations or friends could be traced to give any particulars of the onset of his disease or any previous medical history.

During the time he was in the Mental Hospital no improvement took place in his mental condition and periodic typical major epileptic fits occurred there being 6 in January 5 in February none in March, 1 in April, none in June and 2 in July. There was no prodromal

signs or symptoms of the fits During this period the physical condition deteriorated In June, 1936, a glucose tolerance curve was obtained which gave the following figures —

Fasting blood-sugar	$\frac{1}{2}$ hr	1 hr	$1\frac{1}{2}$ hr	2 hr
308 mg per 100 c cm	360	364	444	400

Sugar was present in the urine throughout the examination On July 20th the opportunity arose of taking a specimen of blood immediately after a fit and this was found to contain 500 mg per 100 c cm of glucose For the reasons mentioned above he was transferred to the General Hospital On admission he was found to be very emaciated, there was considerable mental confusion and he was unable to give any account of himself

Examination—The abdominal reflex was active on both sides plantar reflexes could not be obtained the deep reflexes were absent, the pupils reacted to light and accommodation

Pulse rate 80 no irregularities, heart, normal dimensions sounds clear and closed, blood pressure 115 mm Hg systolic, 80 diastolic There was advanced pulmonary tuberculosis in both lungs

Laboratory reports—Urine contained 9 per cent sugar but no ketone bodies Blood showed secondary anaemia but no eosinophilia Wassermann and Kahn tests negative Stools no ova, amœba, or cysts detected Glucose tolerance curve taken on August 3rd —

Fasting	$\frac{1}{2}$ hr	1 hr	$1\frac{1}{2}$ hr	2 hr
267 mg per 100 c cm	333	340	440	440

Sugar was present in the urine throughout the test Electrocardiogram showed a slightly increased size of the P wave but no other abnormalities Cerebro spinal fluid Wassermann negative

From these examinations the possibility of the fits being due to syphilitic infection was ruled out and it was considered that the condition might be due to a cysticercal infection of the brain The whole of the body was carefully examined for the presence of palpable cysts but none were discovered

On August 11th the skull was X rayed No calcified cysticercal cysts were demonstrated in spite of four examinations, the only abnormality detected

FIG 1—Cysts seen in the left (on the left) and right cerebral hemispheres

being a shallowness of the pituitary fossa Similar X ray examinations of the thorax and abdomen failed to show any calcified cysts Unfortunately the limbs were not submitted to X ray examination

The patient remained in hospital and up to the end of September his condition improved mentally and physically under strict dietetic measures and administration of small doses of insulin so much so that he was able to take a fairly intelligent interest in his surroundings and gained 10 lb in weight In the first week of October he started to run a high temperature and signs of more tubercular activity appeared in his chest and the percentage of sugar in the urine increased in spite of insulin injections He died on Oct 20th

Post mortem report—Chronic ulcerative phthisis left lung and tuberculous broncho pneumonia of right lung with thickened pleura on both sides Impervious splenoidal air sinus In the pancreas the islets of

FIG 2—Photomicrograph of scolex from cysticercus in pars basalis showing double row of hooklets

Langerhans were few and far between and those that were seen were small and atrophic Alimentary canal normal, no tapeworm present

Brain—Weight 2 lb 4 oz, rather small in size An opalescent slightly milky fluid spurted out from the left temporal lobe during the removal of the brain from the cranial cavity A cyst of the size of a small pea with a milk spot was seen in the right anterior central sulcus about 1 in above the point of division of the stem of the Sylvian fissure A whitish nodule of the size of a large pea projecting on the surface of the pars basilaris of the left side (Fig 1, right) Above this the cortex of the posterior ends of the middle frontal gyri was softened The left temporal pole was soft, cystic, and collapsed The gyrus rectus and the medial orbital gyrus of the left frontal lobe appeared to be softened On making antero-posterior vertical sections through the left half of the brain (1) There was a cavity of the size of a walnut in the anterior part of the temporal lobe, its wall was very thin below and had clearly been torn during removal of the brain (Fig 1, left) (2) A cavity about 1 in long, $\frac{1}{2}$ in broad, and $\frac{1}{2}$ in deep was present $\frac{1}{2}$ in above the medial orbital gyrus and gyrus rectus, the wall being ragged (3) An almost circular cavity $\frac{1}{2}$ in in diameter outlined by a capsule was seen in the pars basilaris containing a cysticercus which showed under the microscope a scolex with a double row of hooklets (Fig 2)

DISCUSSION

From the pathological report it seems that the cause of this patient's epileptic fits was a cerebral infection with the cysticercus of *Taenia solium*. It is unfortunately impossible to state the duration of the infection, but we are justified in assuming that it is over 12 months since fits have been present for this period Sections of the cysticercus removed from the frontal lobe show no sign of degeneration and it is reasonable to assume that these were living before being placed in fixing material MacArthur was unable to give any idea of the duration of the infection in his cases In one patient the fits came on during treatment for tapeworm, while in another fits first started four years after removal of a worm

It is interesting to note that in his cases as in the one described, no calcification of the cysticerci was found in the brain, and in the other specimens in the Madras Medical College museum where a brain infestation is present no calcification has taken place Morrison (1934) has described the only case where

calcification of cysts in the brain associated with epileptic convulsions has been found.

SUMMARY

A case is described of epilepsy in a diabetic Indian due to infestation of the brain with *Cysticercus cellulosus*. This is the first noted in an Indian though there have been cases reported in British soldiers. There is a need for research on the life history of this cysticercus cellulosus. The importance of finding some definite cause for epileptic fits in hyperglycemia is demonstrated.

My thanks are due to Dr. H. S. Hensman for allowing me to investigate this case, to Dr. A. Vasudevan for pathological reports, and to Captain L. W. Barnard for the photographs.

ACUTE PAROTITIS AS A MANIFESTATION OF LATENT URÆMIA

By REGINALD T. PAYNE, M.S., M.D. Lond.
F.R.C.S. Eng.

CASUALTY SURGEON TO ST BARTHOLOMEW'S HOSPITAL

It does not appear to be generally recognised that in certain circumstances acute parotitis may be an indirect or even early manifestation of unsuspected uræmia. That this is actually the case has been brought home to me in many instances during the past few years. This type of parotitis is only likely to arise in patients who are already ill from some other disease—particularly in conditions in which latent uræmia may occur—such as gastric hæmorrhage, acute infections, insanity, and in the post-operative state. The uræmia therefore may or may not be of extra renal type and in addition is a type which is not accompanied by œdema. The association between established uræmia and acute parotitis is well known but I do not believe it is recognised that the parotitis may at times be the first sign of a latent uræmia or even that the parotitis coming on after gastric hæmorrhage &c. may have a uræmic background.

Ætiology

In such uræmic states ideal conditions are present in the mouth for the development of an ascending parotitis. The mouth is dry as the result of the suppression of almost all salivary secretion and the tongue and lips are either parched or thickly furled. The bacterial content of the mouth is much increased and it has been demonstrated by Seifert (1926) that this is especially true of the *Staphylococcus aureus* at least in the post-operative type. Bacteriologically this type of acute parotitis is almost always due to *S. aureus*. From the pathological point of view the process is best conceived as a diffuse carbuncular infection of the gland extending along the ramifications of the ducts. This carbuncular nature is well demonstrated in post-mortem specimens.

The prognosis of acute parotitis in these uræmic patients is not good. The presence of some antecedent serious disease and the existence of some

degree or other of uræmia make the outcome uncertain. As regards acute staphylococcal parotitis itself this is always a serious disease owing to the anatomical configuration of the gland and its dense capsule. The recent work of Christiansen (1935) on uræmia as the cause of death after massive gastric hæmorrhage has a bearing on this subject. He has shown that latent uræmia is often the cause of death after hæmorrhage from peptic ulceration. The high incidence of parotitis in this disease which was recorded by Rolleston and Oliver in 1909 suggests at least that the parotitis has a uræmic basis. The factor of buccal infection is obviously an important one leading to acute parotitis and this is brought about largely through the absence of chewing. The latent uræmia that is present in many of these patients leads to considerable suppression of salivary secretion. It is the combination of exaltation of the buccal flora especially the staphylococci, together with absence of parotid secretion that leads to the development of ascending parotitis. The condition is comparable to the development of ascending pyelonephritis after prostatectomy. Rolleston and Oliver say: "None attached more importance to antecedent hæmatemesis than to oral starvation as a factor in the causation of this form of parotitis." This would fit in with the present conception of the sequence of events—namely hæmatemesis, uræmia, parotitis.

Treatment

Acute parotitis as an early sign of latent or developing uræmia is especially likely when the patient already has some antecedent serious disease. I have so often made a diagnosis of uræmia in unsuspected cases on the grounds that the patient had an acute parotitis associated with some other disease that I cannot believe that parotitis is often considered as possibly the first manifestation of uræmia. Treatment of these cases is not considered here in detail, but the parotitis must always be taken extremely seriously since it may well prove a factor bringing about a fatal outcome. If resolution of the condition cannot be brought about very rapidly by conservative measures there should be no hesitation in exposing the gland freely by the usual curved incision and making a series of transverse incisions into the fascia and the gland itself. The absence of any gross collection of pus should not disconcert the surgeon. Pus will probably pour from the wound within 24 hours of operation. In the post-mortem examples of acute parotitis to which I have referred there was no gross collection of pus but the whole duct system of the gland was in a state of purulent infiltration and the gland itself was about six times normal size. In acute parotitis death may occur long before there is any attempt at localisation of an abscess in the gland. Finally recognition of the parotitis as a possible manifestation of uræmia may lead to adequate treatment of the latter.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—The Zunt Fund in accordance with the plan described in our issue of March 20th (p. 730) has allocated £8000 to this hospital. The year's surplus has been used to defray part of the capital expenditure on improvements. The hospital is now affiliated to the Mid Essex Hospital where nurses will complete their training.

CLINICAL AND LABORATORY NOTES

TUBERCULOUS VULVOVAGINITIS

REPORT OF A CASE IN INFANCY

By VALENTINE A J SWAIN, M.R.C.S. Eng

LATE HOUSE SURGEON HOSPITAL FOR SICK CHILDREN,
GREAT ORMOND STREET LONDON

TUBERCULOSIS of the vulva and vagina is the rarest form of clinical genital tuberculosis, and according to Norris (1928) occurs in about 2 per cent of all tuberculous lesions of the genital tract. Clifford White (1917) states that a quarter of the cases of this disease occur in children, adults are commonly affected at the ages of 30-40. The following report of this disease in an infant shows some interesting features.

CASE REPORT

A female infant, aged 17 months, was admitted to hospital on account of having difficulty in passing water. It was first noticed about two weeks before admission that she cried during micturition and seemed to pass little urine at a time. One week later it was noticed that the vulval region was swollen and sensitive to touch.

Past history—A full term baby, only child, birth weight 6½ lb., breast-fed till 8½ months old.

Family history—It was ascertained that there was a strong family history of pulmonary tuberculosis on the father's side. Later it was found that both parents had active tuberculosis; the mother has since died of phthisis.

On examination she was a pale, ill looking child, and under weight (19 lb.). Examination revealed an oedematous and inflamed vulva, there was an ulcerated area on the left postero lateral aspect of the vaginal orifice, this was very tender. The inguinal glands on both sides were palpably enlarged, but not tender nor fluctuant. Apart from a few small glands enlarged in the neck, the child appeared otherwise quite normal.

The urine on admission was sterile. A vaginal smear showed some pus cells and mixed organisms, no gonococci were seen. One week after admission the inguinal glands became swollen and fluctuating. They were aspirated and a few c.cm. of thick blood stained pus was withdrawn, this contained a few Gram positive cocci. A Ziehl-Neelsen film showed many tubercle bacilli, on culture only coliform bacilli were grown. The glands were later aspirated again on several occasions as they refilled. Animal inoculation of the pus produced a tuberculous reaction.

Five weeks after admission the child was examined under an anaesthetic. The inguinal glands were incised and everted. There was an ulcerated area in the region of the left posterolateral aspect of the vulvo vaginal orifice, the right side was slightly involved. The edges were irregular unindurated, and definitely undermined. The base was irregular in depth and on its surface was bleeding granulation tissue. It extended for about 1 in. into the vagina. There was no evidence of any sinus. The cervix uteri appeared healthy and normal. Rectal examination revealed no abnormality in the pelvis. A section of the ulcer margin was excised for biopsy. Dr D. N. Nabarro reported that the section showed well formed giant cells and systems surrounded by lymphocytes, there was widespread endothelial cell proliferation. Staining in a Ziehl-Neelsen film showed scanty tubercle bacilli to be present.

It was thought that there might have been a focus in the urinary tract, primary to that on the vulva. The bladder was cystoscoped by Mr T. Twistington Higgins; there was some urethritis, the bladder neck was some what reddened and congested, both ureteric orifices appeared normal functioning with a clear efflux. It was thought inadvisable to catheterise the ureters in view of the negative findings and the risk of spreading infection. Uroselectan films appeared normal. The urine was

examined from time to time and no tubercle bacilli were found. Other investigations showed Mantoux test, 1/10 000, was positive, Frei's test for lymphogranuloma inguinale was negative. Blood count, white cells 17,500 per c.mm., red cells 3,820,000 per c.mm., haemoglobin 55 per cent, colour index 0.7. A radiogram of the chest revealed a calcareous node at the right hilum.

Treatment—The local condition was treated with X-ray irradiations and soothing applications. In addition, general ultra violet ray therapy was given, as well as general tonics of iron and cod liver oil.

Progress—The child developed subsequently bilateral otitis media following measles, it was a streptococcal infection, she later developed mastoiditis, which necessitated a mastoidectomy, this was followed by suppurative adenitis in the neck. The patient is now having treatment at a sanatorium where she is making very slow but favourable progress in both her local and general condition.

COMMENTARY

Jameson (1935) in a monograph describes this condition fully in its many aspects with adequate references to other reports. The lesion on the vulva usually occurs in people with tuberculosis in other parts of the body. Primary lesions, however, have been reported, but they are very rare, for negative clinical evidence of other tuberculous foci is insufficient grounds for regarding a case as being primary in origin, and many cases post mortem will reveal microscopic evidence of tuberculosis at other sites.

The mode of infection of the lower genital tract in every case is difficult to ascertain. The vulva and vagina may become infected secondarily from above from lesions in the upper genital or urinary tract. Descending spread may also occur from other sites by means of the blood or lymphatic stream. Direct inoculation of the genitalia can occur by contamination with the hands of a phthisical subject, as in a baby requiring frequent attention to its toilet. In adults, the condition can have a venereal origin, but this is uncommon.

In the case described the upper genital urinary tract appeared clinically free from tuberculosis, while the lungs showed evidence of past infection, in that a calcified gland is present in the hilar region. This is not surprising as the child's parents both had active pulmonary tuberculosis and that she was breast fed until 8½ months old. The pulmonary lesion is probably of earlier origin than that of the vulva, and the latter may have become secondarily infected with dissemination of the disease. Alternatively, it is possible that the vulva may have become directly contaminated by the parents during attention to the baby's toilet. For it has been shown by Jameson (1935) at the Stryker Laboratory in New York that the introduction of a strain of tubercle bacilli into the vagina of an animal (guinea pig) can produce tuberculous lesions in the lower genital tract. This is greatly enhanced if the animals are first sensitised by a previous inoculation with a strain of tubercle bacilli. Trauma, also, increases the liability to develop these lesions. Jameson generalises by analogy that "even in humans tuberculosis of the vagina and vulva may be of the ascending type much more frequently than is suspected at the present time," and that "upper tract lesions are usually descending infections." He gives further clinical and pathological evidence to substantiate this statement.

Tuberculosis of this region occurs either in an ulcerative or hypertrophic form, the former is the

commoner. The ulcers may be single or multiple and may vary in character forming confluent ulcerated areas or sinuses. The inguinal glands are involved late as a rule. Dysuria pruritus and swelling of the vulva with some discharge are the commonest symptoms. On examination other tuberculous lesions may be found elsewhere. Diagnosis may be difficult for typical tuberculous giant-celled systems are often scanty in the histological sections and the Koch's bacilli may be few.

I am indebted to Mr T Twistington Higgins for his interest and permission to publish the report of this case which was under his care at the Hospital for Sick Children, Great Ormond-street; also to the pathology department for the various investigations and to Mr D Martin for the photograph.

BILATERAL CYSTIC SWELLINGS OF THE THIGHS OF TUBERCULOUS ORIGIN

By E A DEVENISH M.S. Lond. F.R.C.S. Eng

ASSISTANT TO THE SURGICAL UNIT UNIVERSITY COLLEGE HOSPITAL

A PAINTER, aged 18 was admitted to hospital on June 19th, 1936 complaining of a lump in the upper part of the left thigh.

Eight years before admission he had fractured the left femur in its middle third and about six months after this he noticed the swelling in his left thigh. The lump had gradually got larger and for the last two years he had pain in the region of the lump. The pain was gnawing and was worse at night and on lying down. It was not brought on by walking but running produced some pain. He had never been ill before did not suffer from night sweats and had no history of familial tuberculosis.

He was a well-covered stocky youth and on standing naked the bulging of the upper

FIG 1.—Photograph taken after excision of left cyst. The discoloration of the skin is due to disease.

normal outline of the thigh by about 4 in. The overlying skin was not attached to the mass and was normal in all respects.

Right thigh.—There was a similar swelling in the corresponding situation in the right thigh. This extended well into the buttock, deep to the gluteus maximus, and fluctuation was demonstrable between the swelling of the thigh and of the buttock. The patient had not noticed the swelling of the right thigh.

Hip-joints.—There was considerable limitation of internal rotation of both joints with slight limitation of flexion and abduction of the left joint. The lower limbs were equal in length. No abnormality was discovered on examination of the spine or of the rectum and fluctuation could not be obtained between the swelling of one thigh and that of the other.

Radio-grams of the hip joints and femora showed no abnormality beyond a small oval area of rarefaction in the left great trochanter (Fig 2). A radiogram

FIG 2.—Radiogram of left great trochanter showing area of rarefaction.

of the chest showed evidence of previous tuberculosis in the form of densely calcified glands at both hila and dense shadows in the upper third of the right lung field. There was no evidence of present activity.

Operations.—The swelling of the left thigh was aspirated and thick opaque yellow fluid containing cholesterol crystals and a few polymorphs and lymphocytes was obtained. It was sterile on culture and did not contain tubercle bacilli as was shown by a negative guinea pig inoculation with this fluid. On July 6th the left thigh was explored and a large cyst adherent to the surrounding structures situated deep to the deep fascia of the thigh and extending backwards deep to the anterior border of the gluteus maximus was dissected out. The main cyst communicated by a narrow neck with a small abscess cavity in the great trochanter. This abscess cavity was lined by smooth sclerosed bone and was filled with granulation tissue. Cultures from the cyst fluid and from the granulation tissue were sterile. The wound healed by first intention. On July 30th the right thigh and buttock were explored. An exactly similar cyst was found situated deep to the gluteus maximus and extending anteriorly between the tensor fasciae femoris and the vastus lateralis. Deep to the insertion of the gluteus medius was a separate small abscess cavity lined with granulations and lying over an area of bare bone about 1 in in diameter. No connexion of the cyst cavity with the hip-joint was demonstrable in either thigh. A portion of the cyst wall excised from the right thigh was injected into a guinea pig which 6 weeks later had developed miliary tuberculosis.

Morbidity histology.—The tissue excised consisted of the cyst walls and the granulation tissue everted from the cavity in the left great trochanter. The cysts were identical in appearance both to the naked eye and on microscopic examination. Each consisted of a tough, fibrous wall about 1 in thick, lined on its inner surface by yellow caseous material which when washed away revealed a granular surface like that of morocco leather. The outer surface of the cysts was adherent to the surrounding structures and had been separated from them by sharp dissection.

On microscopic examination the granulations from the abscess cavity in the bone were typical tuberculous granulations. No bone trabeculae were present. The wall of each cyst was composed of three layers (Fig 3): (1) An outer layer of adult fibrous tissue adherent to the surrounding structures. (2) A middle layer of

tuberculous granulation tissue (3) An inner layer of caseous material. An unsuccessful search was made for tubercle bacilli in the sections cut, but the nature of the

FIG 3—Microphotograph of whole thickness of cyst wall ($\times 8$)

lesion was proved by the positive guinea pig inoculation with material from the wall of the cyst.

The cystic swellings in the thighs were almost certainly chronic abscess cavities arising from comparatively small bone lesions. The unusual feature was the symmetry of the swellings which on first sight gave the patient the appearance of having some femoral deformity. This symmetry is explicable on the supposition that the disease began in the great trochanters if, as is probable, the initial bone lesions were embolic in origin. This probability is supported by the presence in the right lung of evidence of an old tuberculous lesion from which the emboli could have arisen.

The case belongs to that class of tuberculous lesions in which a small bony focus is associated with a large abscess in the surrounding soft parts, the commonest example being caries of the spine, in which a small lesion in one of the vertebral bodies is associated with a large psoas abscess.

CASE OF STREPTOCOCCAL MENINGITIS TREATED WITH PRONTOSIL

By I VITFANSON, M R C S Eng

AURAL SURGEON TO EAST HAM MEMORIAL HOSPITAL AND

G KONSTAM, M D, M R C P Lond

PHYSICIAN TO EAST HAM MEMORIAL HOSPITAL, ASSISTANT
PHYSICIAN TO WEST LONDON HOSPITAL

In a leading article in *THE LANCET* (1936) and in an annotation (1937) the importance of trying Prontosil or its derivative *p* aminobenzenesulphonamide in severe forms of streptococcal infection was urged. This has prompted us to publish the following case of hæmolytic streptococcal meningitis complicating acute otitis media, which was treated with prontosil in addition to orthodox surgical measures.

Although it is fully realised that no inferences can be drawn from an isolated case, the favourable result

might encourage others to test this chemotherapeutic agent under similar circumstances. Available statistics bear witness to the heavy mortality in those cases of otitic meningitis in which the cerebro spinal fluid is infected with organisms, particularly where they are sufficiently numerous to be seen in films from the centrifuged fluid. Jory (1935) in 39 cases at St Bartholomew's Hospital of meningitis complicating acute and chronic otitis media reported 11 in which the cerebro spinal fluid contained hæmolytic and non hæmolytic streptococci, 9 of these patients died and 2 recovered. Gangl and Zange (1935) collected 70 such cases, 16 of which contained hæmolytic and non hæmolytic streptococci in the cerebro spinal fluid, 13 of these died and 3 recovered. Neumann (1934) in 59 cases found streptococci in the cerebro spinal fluid in 16 instances, the proportion of deaths to recoveries was as in the previous series 13 to 3.

A boy aged 10½ was admitted to the East Ham Memorial Hospital on Nov. 13th, 1936, with a left-sided otitis media of three weeks' standing. For nine days he had suffered from mucopurulent otorrhœa without pain or tenderness over the mastoid, the temperature did not rise above 99.2° F except on two occasions when it was 100°. On the tenth day he suddenly developed a temperature of 104.6°, without however any exacerbation of his aural symptoms. A left Schwartze operation was performed by one of us (I V) and an extensive osteitis of the mastoid process with pus and granulations in many cells was found. The lateral sinus was not exposed and the lamina of bone covering it was apparently normal, the tegmen antri was removed over an area 6 mm by 5 mm and there was no evidence of extradural abscess, the cells in Trautmann's triangle as well as those in the apex of the mastoid process were cleared out and the operation was completed.

Seven days later the temperature became normal and the wound was healing satisfactorily, the aural discharge having ceased.

On the twelfth day after operation he woke up with severe generalised headache, photophobia, vomiting and a temperature of 104.1°. Kernig's sign with slight neck rigidity was present and the ophthalmic disc margins were blurred. At lumbar puncture the cerebro spinal fluid was under pressure and contained 3600 cells of which the large majority were pus cells. Cocci were seen in films and on culture they proved to be hæmolytic streptococci. The protein content of the cerebro spinal fluid was 80 mg per 100 c cm.

On the same evening the mastoid wound was reopened and Neumann's operation for meningitis was performed, the posterior meatal wall was removed and the middle fossa dura was widely exposed by the removal of the tegmen tympani and antri and that part of the mastoid bone in contact with the dura. The lateral sinus and the posterior cerebellar dura were uncovered and finally the superior angle of the petrous bone was removed. At the termination of the operation the dura from both fossæ was seen to be tense and although it bulged into the mastoid cavity it was not incised.

Nowhere was there macroscopic evidence of disease of the meninges or extension of the osteitis. During the following twenty-four hours he was delirious and by the evening he had sunk into a deep coma. Lumbar puncture was performed and 25 c cm of cerebro spinal fluid which was under increased pressure were drawn, this was followed by general improvement. Three days later a right external rectus paresis appeared but there was no evidence of involvement of the other ear, and the diplopia disappeared two weeks later. The papilloedema at first increased and remained for four weeks after operation despite an amelioration of the symptoms. Convalescence was interrupted by six days of continuous pyrexia and the temperature became normal twenty days after the second operation. Progress was thenceforward uneventful.

Post operative treatment consisted in daily lumbar puncture for thirteen days and the administration of

prontosil 10 c.m. parenterally b.d. and 2 prontosil album tablets orally b.d. The cerebro-spinal fluid became sterile on the seventh day and the cells which at first had numbered 3000 per c.mm. fell to 35 per c.mm. thirteen days after the operation.

Although prompt operation will save a proportion of such cases the moribund condition of our patient

the day after operation led one to expect a fatal issue.

MEDICAL SOCIETIES

ROYAL MEDICO-CHIRURGICAL SOCIETY OF GLASGOW

A MEETING of this society was held on March 19th. with Mr GEORGE H. EDINGTON the president in the chair. He showed a case in which the radial nerve was operated on two years ago for

Traumatic (Fracture) Paralysis

A schoolboy aged 14 was admitted to the Western Infirmary on Jan. 23rd 1935 with fracture in the middle of the shaft of the right humerus having been knocked down by a motor-car a few hours previously. Examination on the following day showed marked musculo-spiral paralysis. The fracture united and the boy was discharged in a splint. Two months later the paralysis had not improved and on March 28th the radial nerve was exposed through a lateral incision and found nipped between the fragments of the bone. The nerve was divided and freed above and below the fracture and through a medial incision the proximal part was displaced to the front of the arm (as recommended by Stiles) and sutured to the distal part under cover of brachialis anticus. Recovery of power was very slow and when the patient was seen towards the end of July 1935 there was little if any change. Electrical testing of muscles involved showed no response to faradism and a weak response to galvanic current. When seen early in October 1936 he had fair use of hand and arm. The limb was much thinner than its fellow. Paralysis of extensor ossis metacarpi and of primi intermedii pollicis was noted. By mid-February 1937 power was greater; the boy was able to play ping pong but was doubtful of trying tennis. If he tried manipulating a heavy object he felt a strain at the wrist. Thumb paralysis persisted and extension of metacarpal-phalangeal joint of index was not so complete as in the left hand. Numbness was present down the radial side of second metacarpal and index and more slightly on adjacent side of thumb and first metacarpal.

The points illustrated by the case were (1) the diagnosis of the precise cause of paralysis was not made out before operation (2) the slow recovery of power (3) the persistence at present date of implication of deep extensors.

Mr ALEXANDER MILLER discussed

Lesions of the Hip and their Treatment

showing lantern slides illustrating the primary and secondary deformities encountered from lesions in this region. He said that diagnosis was only established in doubtful or early cases by careful observation and follow up. The classification adopted was: (a) toxic arthritis (b) tuberculous disease (c) infective arthritis (non tuberculous) (d) pseudo coxalgia (e) traumatic (f) flail hip. The term toxic arthritis was reserved for cases manifesting the hip joint syndrome which cleared up completely following rest and extension. In treatment the

relative values of manipulation extra and intra articular arthrodesis and osteotomy were considered. Mr G. T. MOWAT spoke on

Rapid Histology in Diagnosis

He discussed cases in which errors of diagnosis as to malignancy had been made at the time of operation; in some cases radical procedure had been carried out and subsequently proved to be unnecessary in others malignant tissue had been cut into and an interval had been allowed to elapse while a paraffin section was being made before adequate treatment was carried out. The results obtained in the Glasgow Royal Cancer Hospital from a system of quick histology were described. In most cases definite information was given and in others an intelligent lead was given to the surgeon. Routine paraffin sections were made afterwards and in no case had the diagnosis as to malignancy to be revised. The system was found most useful in doubtful breast cases but was also used in the gastro-intestinal tract and the oropharynx. In suspected carcinoma of the body of the uterus curettage scrapings were successfully used for diagnosis. Methods used were particularly (1) the frozen section (2) Dudgeon and Patrick method and (3) the Ultropak illuminator. The average time taken for diagnosis was five minutes. The results left little doubt of the general efficiency of the methods or of the practical help given to the surgeon.

Basal Metabolism in Hyperthyroidism

Dr A. B. ANDERSON discussed the relationship of the basal metabolism rate (B.M.R.) to the clinical signs of hyperthyroidism. In a series of 140 cases of varied ages and both sexes which were clinically hyperthyroid or suspected of hyperthyroidism the B.M.R. was estimated and compared with the occurrence of clinical signs: enlargement of the thyroid, exophthalmos, tremor, tachycardia, sweating and loss of weight. The tentative conclusions reached were that when enlargement of the thyroid is accompanied by exophthalmos and any other of the clinical signs the B.M.R. will be high in nearly all cases. When enlargement of the thyroid is not accompanied by exophthalmos but all the other signs are present the B.M.R. will be high in nearly all cases but when only two or three signs are present the B.M.R. will be normal in a number of cases. When enlargement of the thyroid is present alone or with only one other sign the B.M.R. will be normal. In tachycardia without enlargement of the thyroid the B.M.R. will be normal in nearly all cases.

WATERLOO HOSPITAL FOR CHILDREN.—At the annual meeting of governors of this hospital it was stated that if a traffic roundabout was made at the junction of Waterloo-road Stamford-street and York-road part or the whole of the hospital site would have to be used. The hospital has a surplus on the year's workings of over £5000 mainly owing to an increase in legacies.

REVIEWS AND NOTICES OF BOOKS

Ions in Solution

THE development of the quantum mechanical theory of the atom has led to important work on the nature and reactions of ions in solution Dr Gurney summarises, in condensed yet intelligible form, the fruits of this work If the book gives an impression of being largely speculative, it must be remembered that the approach is comparatively new and that experimental research directly related to this approach is at present little developed It is unfortunate, however, that the author has not taken more advantage of the frequent opportunities offered to relate his point of view to more old established if by now more barren ones For example, the non existence in solution of certain metals, such as calcium, in a lower state of ionisation (Ca^+) than the normal (Ca^{++}), despite the predominance of the lower states in ionised vapours, is one of the interesting problems here raised Dr Gurney's explanation in terms of the ionisation energies of the solvated ions and of the solvent is no doubt sound, but it is not very helpful to dismiss as "irrelevant" the non existence of salts in which calcium is monovalent In nearly all cases where a metal exists in more than one state of ionisation in solution, corresponding crystalline salts are known, and rarely is a metal found in a crystal (even an anhydrous crystal) in a state of ionisation which is not realisable in solution On the other hand, the discussion of the Debye Hückel theory, though so brief as to be not entirely accurate, is far better balanced than many much fuller discussions which extend the theory in some particular direction while leaving its basis approximations unexamined

The biggest recent advance dealt with is in that part of electrochemistry which thermodynamics cannot reach The standard electrode potentials and oxidation reduction potentials of metals are discussed in relation to thermionic work functions and energies of solvation To the worker in the biological and medical sciences, whose interest in ions is mainly in their permeability to membranes, and their influence on colloidal dispersion and on ionisation of weak acid groups in complex molecules, the book is of no immediate practical value, because quantum mechanics has as yet little to say on these problems

Morphologische Pathologie

By Prof Dr WERNER HUECK, Director of the Pathological Institute of Leipzig University Leipzig Georg Thieme 1937 Pp 818 R M 52

Prof Hueck breaks away from tradition in the arrangement of subject matter There have been truants before among text books in pathology, for example, MacCallum's work is based on the idea that all pathological changes are the result of some form of injury, this attitude brings with it a liability to teleological thinking Prof Hueck, being a strict causalist, has taken the opposite point of view He discusses the whole of general pathology on a purely morphological basis, and in fact the book may be regarded as a continuation of Oertel's "Introduction to Pathology" It is interesting to find so

many problems approached from a logical standpoint instead of from one which elevates heuristic ideas to the level of final explanations

The book is in two parts the first on general principles, gives an admirable account of the potentialities for differentiation of the mesenchyme and its relation to pathology, and excellent chapters on stone formation and tissue regeneration The section on tumour formation is noteworthy for its comparison between the connective tissue tumours and normal mesenchymal histogenesis, the absence of any adequate account of the systematised blastomata is disappointing The second part of the book deals with "related morphological pathology," which is almost the same thing as what is usually known as "special pathology", no attempt is made to mention lesions in every organ, but a few of the more important disease processes are discussed in detail For example, the account of pulmonary tuberculosis in its various forms, together with its complications—tuberculous enteritis, miliary tuberculosis, and amyloidosis—is excellent, other sections worthy of comment are those on disease of the heart and arteries, the stomach, and the liver This latter section reveals an interesting contrast between German and Anglo American teaching Prof Hueck accepts without question the evolution of a sub acute hepatitis into a chronic stage, yet in nephritis there is no suggestion that an acute nephritis may pass through a subacute oedematous stage before the final uræmic state, "nephrosis" and nephritis are kept distinct, and focal nephritis is not mentioned

A new book of such a revolutionary nature—perhaps revivalistic would describe better a return to the best teachings of "cellular pathology"—is unlikely to maintain throughout a proper balance in the allocation of space or to avoid omission of relevant facts Here endocarditis is merely classed as simple, verrucous, ulceropolypous, or fibrous with little consideration of ætiological factors, the account of endocrine dysfunction in relation to constitutional morphology is too short, and the chapter on leukaemia and anaemia is below the standard of the rest of this stimulating book We commend the instructive diagrams, drawings, and photographs, and the lavish use of colour printing

Venereal Disease

Practical Methods in Diagnosis and Treatment Third edition By DAVID LEES, DSO, MB, DPH, FRCS, FRCP Edin, FRSE Edited and revised by ROBERT LEES, MB, FRCP Edin, Assistant MO for VD to Edinburgh Royal Infirmary and Edinburgh Corporation Edinburgh E and S Livingstone 1937 Pp 608 15s

This good text book on venereal disease has now been brought up to date without having been enlarged The sections which deal with the clinical manifestations of syphilis contain many excellent photographs, including some in colour, which are likely to be of great value to those who seldom have access to this type of clinical material The views expressed on treatment and on standards of cure are in the main orthodox and are set out in a clear and practical way The detailed statement of recommendations for treatment in all stages of syphilis are especially to be commended There are two unexpected omissions The important condition of metastatic mites

secondary to gonococcal infection is barely mentioned and we can find no reference to trichomonas vaginitis in connexion with the differential diagnosis of vaginal discharges of inflammatory origin. On most other subjects the information given is full and complete.

It is unfortunate that some of the methods of expression are slipshod and ungrammatical. More careful proof reading would have excluded such lesser sources of irritation as prostrate gland. These faults should not be allowed to obscure the value of this comprehensive work in which sound theoretical knowledge and wide practical experience are combined.

La vésicule biliaire et ses voies d'excrétion

Second edition By M. CHIRAZ, Professeur Agrégé à la Faculté de Médecine de Paris and I. PAVEL, Maître de Conférences à la Faculté de Médecine de Bucarest. Paris: Masson et Cie 1936. Pp 860. Fra.120.

It is ten years since this standard text-book on diseases of the gall bladder appeared and the second edition necessarily contains important changes. These concern particularly the physiology of the gall bladder and the mechanism of Oddi's sphincter, the etiology of gall-stones, the mechanism of hepatic colic and the bacteriology of cholecystitis. For the chapter dealing with the radiology of the gall bladder Dr A. Lomon is responsible and the reader will find therein an excellent series of illustrations. A considerable bibliography enriches each chapter and there is a full index of authorities as well as of subjects.

Studies in Cardiovascular Regulation

Lane Medical Lectures By G. V. ANREP, M.D. D.Sc. F.R.S. Professor of Physiology, Medical Faculty, Egyptian University, Cairo. London: Humphrey Milford, Oxford University Press 1936. Pp 118. 10s. 6d.

In this monograph Prof Anrep clearly describes the many important advances recently made in our knowledge of the way in which the heart exactly adapts itself to the work demanded of it of the respiratory influence on the heart-rate; and of the coronary blood flow. In a final chapter the blood flow through skeletal and plain muscle is shown to undergo during muscular contraction changes similar to those in the coronary flow during the cardiac cycle. Far from being the master of the circulation the heart is to day regarded as its highly efficient servant, its rate and output being dictated by a variety of reflexes the receptors of which are situated in the walls of the cardiovascular system itself. Prof. Anrep gives an interesting account of how after much controversy the carotid sinus was recognised as an important agent in the control of blood pressure and heart rate. With the aortic and probably also the left ventricular wall and the carotid body the carotid sinus forms the chief vaso-sensory area on the arterial side. On the venous side, in the auricles and right ventricle are receptors which are held to have exactly opposite effects. The complex effects of the impulses from lung tissue and of central discharges from the respiratory centre on the cardiac rhythm are discussed in detail. Their bearing on clinical problems is not yet clear. The sections on the coronary blood flow deal not only with matters of importance to the physiologist such as the effect of systole on

the flow but also many which directly concern the clinician and cardiologist for example the rich dual innervation of the coronaries the reflex constriction which occurs in them when the carotid sinus is stimulated, the effects of certain drugs and the atypical reactions when they are sclerosed. Prof Anrep has contributed largely to cardiovascular physiology. His Lane lectures are a record of his personal observations including those arising from important experiments which he has been able to carry out in Egypt on the human heart obtained soon after death.

1 Practical Physiological Chemistry

For Medical Students By G. M. WISHART, D. P. CUTHBERTSON and J. W. CHAMBERS. Glasgow: John Smith and Son Ltd. (26 Gibson street Glasgow W.2) 1936. Pp 125. 3s. 6d.

2 Laboratory Experiments in Physiological Chemistry

By ARTHUR K. ANDERSON, Ph.D. Professor of Physiological Chemistry, the Pennsylvania State College, London: Chapman and Hall Ltd 1936. Pp 234. 7s. 6d.

1. DESIGNED for use with a forty hours course in practical biochemical work, this excellent little book is eminently suitable for this purpose being concise and accurate. The omission of the estimations of phosphate and sulphate in urine is regrettable and sodium hydrosulphite is preferable to ammonium sulphide as a reducing agent in the study of the blood pigments. This is an outstanding little book.

2. This may be described as the text-book interrogatory and local; interrogatory because the reader instead of being told what the result of an experiment should be is questioned by the author on that very point local because the reader is for example exhorted to obtain from the instructor in a dry flask the sample of vinegar to be analyzed. It is possible that in other places than those familiar to the author other customs may obtain and the instructor not be so well provided. In explanation of the sentence (p. 40) by means of a clean graduate add 240 c.c. of water to a beaker it is a measuring cylinder and not the instructor which is to be put to use.

Physical Diagnosis

By RALPH H. MAJOR, M.D. Professor of Medicine in the University of Kansas. London: W. B. Saunders Co 1937. Pp 475. 21s.

This valuable text book on physical diagnosis embodies fifteen years' experience in teaching by an enthusiast for clinical medicine. Though the personal element is essential for teaching at the bedside it can be tiresome and pedantic in print but Prof Major is not guilty in this way. His tone is not didactic and he makes use of all the recognised authorities and recent work with frequent quotations and extensive lists of references. His admiration for the pioneers of diagnosis leads him to quote their original descriptions in many places but the emphasis is fortunately not on the past. Full credit is given to such valuable advances as the X-ray, the electrocardiogram and the phonogram in explaining the significance and the physical basis of signs. The views expressed are on the whole in line with orthodox British teaching though as is natural where experience depends on local observation material points of disagreement will be found; for example

pathological findings in this country do not suggest that the diagnosis of aortic insufficiency with a Flint murmur is more often correct than that of the combined lesion with mitral stenosis. The statement that the wrist drop in lead poisoning is due to a paralysis of the ulnar nerve is of course merely a careless error.

Though there can be few practitioners who would not find interest in this work, and no teachers of medicine who could not pick up a wrinkle or two from it, it has two disadvantages from the point of view of the student for whom it is intended. First, it is too long, aspects of disease other than physical diagnosis might well have been left out, since they could not be discussed adequately in the available space. The benefit derived from learning the signs necessary for a diagnosis of aortic stenosis for example is nullified if the student goes away with the impression that it is caused equally commonly by syphilis, arterio sclerosis, and rheumatism. Secondly, it is important that the student should know which physical signs are nowadays regarded as significant and reliable, this is not always made sufficiently clear, and the historical emphasis may encourage the seeker after strange signs who may miss dilated and pulsating veins in the neck when bending down in search for Broadbent's sign. On the other hand the many excellent photographs, the helpful diagrams, and, above all, the impulse of Dr Major's enthusiasm may transmit to the student the thrill which will send him to the bedside, there to look, listen, and feel for himself.

Physical Therapeutic Methods in Otolaryngology

By ABRAHAM R. HOLLENDER, M.D., F.A.C.S., Associate in Laryngology, Rhinology, and Otolaryngology, University of Illinois College of Medicine. London: Henry Kimpton 1937. Pp 442. 21s.

Dr Hollender has had the help of ten collaborators, but is himself responsible for the larger part of this massive work. A preliminary section deals with the physical characteristics of the various agents under discussion and the apparatus used in their production, the main part of the volume is concerned with the numerous diseases of the nose, throat, and ear in which these methods may be employed, and is followed by a few miscellaneous chapters. Among the latter is one by Chevalier L. Jackson on endoscopy, and another on hearing aids by Prof. Horace Newhart which, although interesting, have little bearing on the subject of physical therapy. Prof. Francis Lederer has contributed to this part of the book two chapters on neoplasms, in general he favours diathermy, or electrodissection, but gives no detailed description of the various forms of tumour nor of the technique of their individual treatment. This criticism may also be applied to his references to treatment by radium and X rays, where details of application and dosage are not discussed, of laryngeal carcinoma he merely says that radium has proved to be an ineffective therapeutic agent.

It is difficult to decide what methods should be included within the term of physical therapy. From this book the galvano cautery and all forms of spa treatment and inhalation therapy are omitted. All the methods here dealt with, except the use of radium, involve the use of electrical apparatus, and include such various procedures as ionisation, diathermy in all its forms, short wave diathermy, infra red and ultra violet irradiation, and X rays. These new

methods, as opposed to older forms of treatment, are advocated with a degree of enthusiasm which some will think exaggerated, notably where short wave radiation is hailed as "perhaps the most important contribution since Roentgen's epochal discovery," where diathermy is recommended for the reduction of the inferior turbinates, and the galvano cautery is condemned because in unskilful hands it may cause adhesions. A detailed table of contents is provided, as well as a full index. The book contains useful information on the treatment of a great variety of diseases by these methods, and will be read with interest by laryngologists.

Rural Health Practice

By HARRY S. MUSTARD, M.D., Associate Professor of Public Health Administration, Johns Hopkins University. New York: The Commonwealth Fund, London: Humphrey Milford, Oxford: University Press 1936. Pp 603. 17s.

THE Local Government Act of 1929, by requiring all future appointments of medical officers of health to be on a full time basis, has inaugurated a new type of expert in rural hygiene to whom Prof Mustard's book will be most valuable. Such an expert should have no difficulty in separating common ground from that which represents differences between American and British practices. In the United States also part time public medical officers, often appointed for political or charitable reasons, are now giving place to full time experts having some security of tenure of office and therefore the time and inclination to make themselves expert in their particular branch of medicine. This is the justification for this work, which is compiled on original lines. Prof Mustard is one of America's foremost hygienists and is almost as well known in Europe as in the States as an authority on rural hygiene—because he says he has "already made most of the mistakes which it is possible for a rural health officer to make." This book is full of sound advice and is wittily expressed.

NEW INVENTIONS

A MODIFIED RECTAL BOUGIE

THE modified Wales's rectal bougie here illustrated is designed for the purpose of dilating high strictures of the rectum. It is not safe in such a situation as the upper end of the rectum to use rigid metal dilators, or any form of dilator that cannot be passed through

the stricture under full sight. The bougie is made of soft rubber in gradually increasing sizes and can be passed through a large rectal speculum or preferably an operating sigmoidoscope. The difficulty of using soft rubber bougies in these circumstances is that they buckle up, but this bougie has a hole reaching not quite to the end into which a stylet can be passed to stiffen it, and to make it possible to guide it in the desired direction.

The bougie has been made for me by Messrs Down Bros, Ltd, St Thomas's street, London, S.E.

J. P. LOCKHART MUMFERY, F.R.C.S. Eng.
Emeritus Surgeon to St Mark's Hospital for
Diseases of the Rectum

THE LANCET

LONDON SATURDAY APRIL 10 1937

PSYCHIATRY IN VOLUNTARY HOSPITALS

As part of its rebuilding scheme St George's Hospital hopes to equip itself with a psychiatric clinic of 50 beds. The idea of incorporating such a clinic in an undergraduate teaching hospital has such striking advantages that it is indeed remarkable that it has not received effective expression before now. Most of these hospitals now have psychiatric departments but these are concerned mainly with out-patients. From 1923 on the governors of St. Luke's Hospital maintained for a time two small wards for acute mental cases at the Middlesex Hospital but now in all the London teaching hospitals taken together the beds allocated to psychiatric cases add up to only about a dozen and even of these not all are adapted to the reception of refractory or overtly psychotic cases. In the course of his training the average student has little opportunity to observe the full course of mental illness. If he is sufficiently interested to attend regularly the psychiatric out-patients department he can see a sample of mentally abnormal patients at perhaps weekly intervals for a period of from three to six months but this is a poor substitute for the opportunity to observe them in a bed from the moment of admission to that of discharge. The effect of the existing system is that the student obtains his impressions of psychiatry in heterogeneous ways. As he imbibes his general medicine he will learn how important is the psychological factor in physical diseases in the department of psychological medicine he can if he wishes familiarise himself with the common neuroses in the habitues and hangers-on in these departments he will make acquaintance with the chronic neurotic and will appreciate how complete can be the dependency of such persons on doctors. He will see an occasional psychotic case referred to the department for an opinion or retained as an out-patient if certification is not deemed necessary. But with the psychotic requiring care and control he will have very little contact except at periodic demonstrations usually held at a place far removed from the scene of his usual medical studies. Though he may be expected to have a knowledge of the psychoses sufficient to answer a few regularly set questions in the final examinations his attitude after qualification can frequently be summed up in the view that neurotic patients are a tribulation and psychotic patients a class by themselves. Of these he retains from a course of demonstrations an impression comparable to that obtained by a visitor from a series of visits to the Zoo.

In the field of neuroses a practitioner's reluctance or incapacity to deal with the cases that come under his care is reflected in the enormous waiting

lists of organisations such as the Institute of Medical Psychology and in the field of the psychoses there results from the existing system a popular conviction that mental illness carries a stigma which does not attach to physical disease, and that certification is a kind of disgrace. To this attitude of mind is attributable the change of name of some well known hospitals for example Hanwell Hospital becomes St Bernard's Hospital. Even if a student is specially interested in psychiatry it is only after qualification that he will be able to obtain a comprehensive first hand experience of the total range of mental disorder. As a part of such experience the neuroses and psychoses between which a fundamental distinction is commonly and erroneously drawn should be studied simultaneously. Though admirable facilities exist for such study at the Maudsley Hospital, they have not hitherto been available at the undergraduate teaching hospitals. In the Scandinavian most north European countries and in America the medical profession is more effectively equipped to deal with mental illness before qualification. A psychiatric clinic with beds is usually incorporated with or closely affiliated to the general hospital. The advantages of this system are felt equally by the medical profession and by the public. The student is familiarised in the clinic with the principles of diagnosis and treatment of the psychiatric cases potential or actual which he will encounter in his later life and the interests of the able and ambitious student are directed to psychiatry in which an opportunity is provided of obtaining what we would call a house appointment at his teaching hospital. The specialty is benefited by obtaining recruits of good calibre and the needs of the public are well catered for.

Many years ago the late Dr JAMES COLLIER organised a course of neurological demonstrations at St George's Hospital which since his death have been continued at fortnightly intervals by Dr ANTHONY FEILING. These are not confined to students of the hospital indeed they have been attended by large audiences from outside. For some months psychiatric demonstrations have alternated with the sessions devoted to neurology and have been conducted by Dr DESMOND CURRAN with the generous assistance of the senior staff of the Maudsley Hospital. It is a wise plan to provide a nucleus round which the department can expand when facilities are available and to familiarise local doctors with the idea that expert consultants are to hand. We wish the scheme every success and will watch its development with interest. And it may be noted with gratification that an anonymous gift of £,000 has already been received towards the cost and equipment of the department.

INFECTION THROUGH THE OLFACTORY MUCOSA

It has lately been shown in America that susceptibility to infection with certain viruses can be reduced or abolished by treatment of the

olfactory mucosa with solutions of tannic acid, alum, or picric acid. It has been suggested that this means might be of use in the prophylaxis of poliomyelitis and possibly also of other infections that gain entrance by the nose. In this connexion it is useful to have a report by Dr GEOFFREY RAKE¹ from the Rockefeller Institute. His object was to learn how micro-organisms gained the tissues when deposited on the olfactory mucosa and to this end he first studied the absorption of prussian blue administered to mice intranasally. The method is not a new one, having been used for a somewhat similar purpose by CLARK and also by OLITSKY and COX, and like them, RAKE found that the absorption of the particles of dye was extremely rapid. Within two minutes it was seen in the lymphatics and blood-vessels of the olfactory submucosa and had reached the sub-arachnoid space. Apparently the pigment was absorbed by more than one route. Some of it passed inwards between the cells of the olfactory mucosa, but the larger part was taken up by the olfactory nerve cells, from there to be dispersed again to the surrounding tissues. This was clearly brought out by experiments in which the mice had been given a preliminary intranasal application of 0.8 per cent tannic acid, for in these animals, although the dye reached the subarachnoid space just as rapidly though in less amount, the olfactory nerve cells were almost devoid of prussian blue. RAKE noted also in these treated mice that, although they showed no nasal discharge during life, when they were killed and examined a thick exudate of mucus and leucocytes covered the olfactory mucosa and turbinates and histological sections revealed obvious signs of inflammation. Experiments with bacteria—the pneumococcus and *Bacillus enteriditis*—showed that both these pathogens reached the brain as rapidly as the pigment, but that, unlike pigment, they travelled between the cells and not via the neurones. This observation explains previous work² showing that intranasal administration of tannic acid to mice confers no protection against pneumococci given by the same route. In the case of viruses RAKE found that a pantropic virus like that of equine encephalomyelitis reached the brain just as quickly as did pigment or bacteria, whereas strict neurotropes like the viruses of St. Louis encephalitis, louping ill, and rabies took 24 hours to do so. Presumably all four viruses were taken up by the olfactory nerve cells but the strictly neurotropic ones were held there and passed slowly inwards to the brain, whereas the pantropic equine encephalomyelitis virus, like pigment, left the olfactory neurones and travelled to the brain by the more rapid routes represented by the tissue spaces and lymphatics.

The practical lesson of this work seems to be that treatment of the olfactory mucosa with tannic acid or similar preparations is likely to be most effective against a strictly neurotropic virus and ineffective against bacterial invasion. It also sounds a note of warning in that a very definite

inflammatory response resulted in the mouse from the nasal instillation of tannic acid. This would make one hesitate to advocate such a procedure in man, for repeated applications of these preparations are required to give protection and the risk of producing chronic change resulting in an atrophic rhinitis cannot be excluded.

VOX POPULI

THE People's League of Health, having made its voice effectively heard for many years in support of several good causes, has decided to add to their number. It was in 1917 that Miss OLGA NETHERSOLE founded the League, and its achievements were indicated at a luncheon recently given in her honour¹ when Lord LEVERHULME foreshadowed an appeal to be launched at the Guildhall on Thursday of next week at which the Lord Mayor of London will preside. The essential purpose of the League has been the collection and distribution of knowledge—knowledge based on scientific foundation and presented in attractive form. The Safe Milk campaign, with its inquiry as to the best means of eliminating tuberculosis from milk, yielding cows and as to the value of milk as food for school children, is the best known of the League's activities, but the League has been invited to draw up a memorandum on the composition and description of foods, and it has initiated a study of maternal mortality and morbidity in cooperation with nine metropolitan hospitals. The League, while proposing to continue these campaigns and its activities as a bureau of health information, is now propounding eight other subjects in its new programme.

It has in prospect a centre for the practical demonstrations of a scheme for the eradication of tuberculosis from dairy herds. It proposes to develop a central almoner service where information can be obtained about everything like child welfare clinics, nurseries of various kinds, or the adoption and boarding-out of children. It intends to examine the conditions under which infants and older children are received by foster-mothers. It contemplates a survey of children under treatment at orthopaedic hospitals and other institutions where surgical tuberculosis is treated. It hopes to press upon the Government the value of compulsory periodical medical and dental examinations of all persons insured under the National Health Acts. The position of the expectant mother under these Acts is to be made the subject of inquiry. The League has already emphasised the psychological aspect of unemployment and considers the time has come when no person should have scars left on his mental and physical health simply as a result of being unemployed. Finally the League will continue to study all proposals, legislative and otherwise, relating to the health of the people and the circulation of information designed to promote it. The appeal for £50,000 now being made should meet with a ready response in view of the League's past record and present intention.

ANNOTATIONS

A QUESTION OF NEIGHBOURLINESS

MANCHESTER is learning afresh the precept that almsdoers should not let their left hand know what their right hand doeth. One form of public benevolence is the relief of pain and sickness by hospitals; another is the relief of unemployment by labour exchanges. Manchester has a Royal Infirmary with a central branch where two eminent honorary surgeons and a resident staff do their best for very serious cases to the number of 1300 to 1400 per annum. The Minister of Labour in spite of protests, has begun to erect alongside this central branch a large building which will deprive the patients of light and air will cause the wards to be overlooked from scores of windows and will collect in a narrow space at close range a crowd of possibly 300 unemployed not always perhaps the most quiet and orderly of gatherings. The Minister is doubtless not his own master. He wants to find a home for the divisional office for the North West of England the Central Employment Exchange for Manchester and other departmental offices. His Majesty's Office of Works owns an empty space bought soon after the war adjoining the central branch of the infirmary. Naturally the Minister of Labour wants the best site; naturally the Office of Works has it available already. Between them they can tell the Royal Infirmary that its patients have been lucky all these years to look out upon a vacant space, and that whereas the central branch is inconveniently situated and may some day have to move, the new employment exchange will be a permanent adornment of the city. What the Minister of Health thinks of the dwarfing and obstructing of the Royal Infirmary we have not been told. What the medical board and the local medical officer of health think about it we know. The Minister of Labour has been assured on good authority that his building will make the central branch unsuitable for inpatient accommodation and gloomy and depressing for a casualty department. He has been asked either to alter his building or to put it somewhere else or to take over the Royal Infirmary's building and help the trustees to replace the 54 beds which in that event would be lost. He replies that he has considered all alternatives and has rejected them; he cannot wait any longer the building must begin.

The dwellers in a peaceful part of the Thames Valley lately learnt that a munition factory was to be established in their midst. They protested successfully; the department concerned gave way at the eleventh hour in spite of having repeatedly stated that no other place would do. Manchester has been less lucky. The Minister of Labour could not change his mind. Four years ago with the obvious sympathy of the Ministry of Health Parliament passed an Act to aid the fortunes of the Royal Infirmary. To-day another Ministry insisting firmly on its legal rights takes a step which will have the opposite effect. The trustees of the hospital have put forward a reasonable argument. The infirmary and the employment exchange they say are alike public services paid for out of public money. If the expenditure of the infirmary is not met from one set of pockets it must be met from another. If the infirmary had in fact been the home of a Government department conducting important research in health matters, the Minister of Labour would have refrained from neutralising its usefulness. If he now finds himself destroying the value of Manchester's only

central hospital ought he not either to hold his hand and change his plans or else help it to find proper accommodation elsewhere?

ANÆMIA AND THE PITUITARY

THE production of acute ulceration of the acid secreting area of the stomach of rabbits by injection of massive doses of a posterior pituitary extract was first described by Dodds and his collaborators¹ in 1934. In a further communication² they discussed the influence of large doses of pituitary extract on the blood and suggested that the macrocytic anemia it induces may be due to increased blood destruction and consequent regeneration their findings leading them to postulate a hormonal connexion between the pituitary the gastric function and the blood. On the assumption that the anemia may be due to blood dilution from the antidiuretic action of the pituitary Gillman and Goodman³ have studied the blood changes in rabbits resulting from large doses of the extract. They find that much dilution does in fact occur—the hemoglobin the number of red cells and the plasma osmotic pressure being all reduced—while cell destruction is sometimes superimposed upon it. The macrocytic anemia was similar to that described by Dodds but they attribute it to the altered environment of the cells during plasma dilution making them more fragile. In the test tube the red-cell fragility was actually reduced by lowering the plasma osmotic pressure yet in vivo cell destruction was increased. All these changes could be prevented by dehydrating the animals before injection of the pituitary extract. McFarlane and McPhail⁴ have also produced anemia by injections of pituitrin into normal and hypophysectomised guinea-pigs, but they did not investigate the anemia further. They state that they have failed to find any hormonal connexion between the pituitary the gastric function and blood formation.

in the country, so depriving the famous Oxford marmalade of the little bit extra which might have merited so much to those who endeavoured to uphold the prestige of the University upon the Isis. The latent possibilities in drugs, the mystery and the magic, naturally invite still greater expectations from such extremes as the simplest kitchen ingredients and the most obscure secrets of native witch doctors. At a recent meeting of the Berlin Medical Society Prof. Helmut Drenning, director of the Morbit Medical Clinic, claimed¹ an increase of physical capacity and endurance by 30 to 100 per cent from the administration of natron, being bicarbonate of soda, to hasten the elimination of acids, especially lactic acid. The simplicity of the method recalls the remarkable effect of delaying fatigue ascribed² to acid sodium phosphate during the late war when this salt was administered to the German storm troops. Investigations undertaken in America³ failed to confirm the claim. Any advantage derived from the phosphate was due to the increased sense of well being or the lessening of tiredness created by its stimulant action on the intestinal tract; there was no measurable increase of muscular efficiency, nor was the onset of fatigue delayed. And this was confirmed by the personal experience of a well known physician athlete in this country. It is common experience that in moments of stress the physical capability may be increased to an extent hitherto unexpected and almost unbelievable. In everyday life there are inhibitions which, acting like a governor, prevent a maximal effort being put forth; any drug which can diminish sensitiveness, paralyse the appreciation of fatigue, and eliminate the faculties of judgment and self preservation might have the effect described as doping in the case of race horses. On the continent it seems to have been necessary to issue a warning to athletes not to dope themselves.

DRAINAGE OF THE PERITONEAL CAVITY

THERE is something to be said for J. E. Jennings's contention⁴ that so called drainage of the abdominal cavity is usually "superstitious and ineffective packing." It is well established that none of the ordinary methods gives anything approaching general peritoneal drainage, but how far is this fact recognised in practice? Discussing Dr. Jennings's paper, Dr. W. B. Parsons of New York said that five surgeons suddenly confronted with the problem might be expected to give five different opinions about the right way to drain an appendix or gall-bladder, and as to why a drain is wanted in one case and not in another. Since localised drainage is alone possible the indications for insertion of a drain are definitely restricted. The most obvious benefit to be gained is the formation of a "path of least resistance" for localised infection actual or anticipated. Jennings holds that tubes or gauze strips—the materials usually employed—irritate the tissues producing an exudate which at the same time tends to block the drain and encourage walling off of the infection. Most drains act partly as packs, and unless the infective process is localised their value as drains will be nil. In his opinion the indications for localised peritoneal drainage are, broadly speaking, two. In the first place, drains may be inserted at the end of operation to remove exudate, blood or bile collecting at the operation site or to serve as sentinels where a leak is feared at a line

of suture in a hollow organ. Secondly, they may be used to remove infected exudate, such as pus, in cases of localised peritonitis. Here the amount of drainage that actually takes place through the tube or gauze is slight, and the important effect of the drain is that a track is made down to an "extra peritonealised" cavity. The use of a material with the minimum of irritation to the tissues will reduce or prevent the formation of localising adhesions, and such a material Jennings claims to have found in raffia. Selected strands are chosen, cleared of strangling fibres, washed in boiling soap and water, cut into standard lengths, knotted in hanks of twenty strands, and wrapped in muslin packages. Sterilisation is carried out on three successive days, and the required strands are reboiled just before use. Raffia has a capillary action and is very strong; it is also smooth and inflicts the minimum of injury during removal. Jennings has employed it for twenty years and has found it especially useful where a drain is required simply to remove an exudate, and where no advantage can result from its acting as a pack.

VITAMIN-B DEFICIENCY AND THE HEART

HEART failure resulting from vitamin B deficiency has long been known in the East as an accompaniment of beriberi and pellagra. An early view was that, like the neurological symptoms, the heart affection was secondary to a neuritis, the vagus nerves being the site of the lesions. When in 1927 Wenckebach discussed this subject in our columns,¹ he suggested that the functional failure of the beriberi heart was due to oedema of the myocardium. Weiss and Wilkins² have now come to the conclusion that similar deficiency states, accompanied by cardiac disease, are not uncommon in the United States, and they have been able to collect 97 cases, 12 of which they observed personally. As evidence of vitamin deficiency they accepted polyneuritis, pellagra, dermatitis, glossitis, and gastro intestinal disturbances, and a history of an inadequate diet. The heart lesions associated with these conditions could not be put down to other recognised factors, and the symptoms and signs of such lesions improved after administration of vitamin B. The circulatory symptoms were variable, but prominent among them were dyspnoea, regular tachycardia, palpitation, and exhaustion. These, with excessive arterial pulsation, loud sounds over the arteries, and a rapid circulation rate, are features that recall the circulatory changes in goitre and also in some functional nervous disorders. Such symptoms were found especially in association with polyneuritis. Syncopal attacks, exaggerated sensitivity of the carotid sinus, vaso motor collapse, and bradycardia in convalescence were also observed and were regarded as signs of nerve lesions. On the other hand, some of the symptoms often encountered are more characteristic of hypertensive and ischaemic heart disease—for example, gallop rhythm and congestive failure with normal rhythm. Cardiac enlargement was usual and changes in the electrocardiogram were rarely absent; these included low voltage, altered T waves, premature beats, and occasionally auricular fibrillation. Histological studies on a few cases that came to autopsy showed myocardial changes like those described by Wenckebach, but these are held by Weiss and Wilkins to be in no way specific. The treatment of these cases is simple enough, consisting in rest and

administration of vitamin B₁—if necessary giving the crystalline B₁ by injection. Improvement was striking signs of congestion for example disappearing far more rapidly than might be expected in other forms of congestive failure the electrocardiogram also quickly regained its normal form. In animal experiments such effects are even more remarkable gross electrocardiographic changes seen in rats suffering from vitamin B₁ deficiency could be abolished within twelve hours by an injection of crystalline B₁ (Zoll and Weiss²).

This paper by Weiss and Wilkins is of great interest and the six cases they record in detail would be hard to explain in ordinary ways—except perhaps one in which the patient appears to have had hypertension. Five of these six patients had alcoholic polyneuritis now regarded as directly due to lack of vitamin B₁, and it is possible that inquiry into such cases in this country though now of course relatively rare might reveal significant cardiovascular disturbances.

JUDGMENT AND REASON

Dr Hutchison's little trilogy on the fundamental principles of clinical medicine³ has reached us in its second edition. For the rounded felicity of their style and the practical wisdom of their content his essays are well worth re-reading. The preface puts words into the reviewer's mouth although there is nothing in them that has not been said often before there is also nothing in them that will not bear saying again. In the essay on diagnosis we read that this art involves the use of observation of knowledge and of judgment and by judgment is meant an intuitive faculty of distinguishing the relative importance of things. The use of reason is not mentioned which is a little discouraging for those who labour in the faith that scientific methods and scientific ways of thinking have much to contribute to medicine. Not the most ardent of them however can deny that medicine as it is practised, is still largely empirical. And there is certainly the danger which Dr Hutchison would guard against that the art of dealing wisely with the sick may be perverted by pseudo-scientific enthusiasms. Most of us would be the better for turning over these pages again and a copy would not come amiss as a gift for some medical student of our acquaintance who may be approaching his final examination.

URETERO-INTESTINAL IMPLANTATION

Eighty years have elapsed since Simon made the first attempt to divert the urine into the bowel and during these eighty years more than a thousand such operations have been performed. Hinman and Weyrauch⁴ who have written an elaborate account of the methods used complain that previous reviewers have laid too little stress on the surgical principles on which a satisfactory operation must be based. An historical review can be of use to the surgeon to day only if it teaches the way to implant ureters more successfully than has been done in the past. The conclusions Hinman and Weyrauch themselves reach are not altogether optimistic. They are left with a feeling of disappointment at the lack of

improvement with the advent of newer methods and greater experience. It would seem that every surgical technique imaginable has been tried. Of the eleven methods listed, submucous implantation has given the best results yet many questions about it still require answers. What are the factors that produce localised necrosis of the intestine or perforation and tearing-out of sutures? Why is anæmia infarction extensive necrosis diffuse ureteritis, or dilatation of the ureter found at autopsy? Too often the answer to this will be failure on the part of the operator to obey the simple well known rules of intestinal and ureteral surgery. The only layers that are safe for suturing are the submucous layer of the bowel and the adventitia of the ureter. Sutures cannot penetrate the lumen of either without danger. Their blood supply cannot be disturbed to any great extent neither can they be unduly bruised twisted or displaced. These are some of the principles that must be followed if postoperative accidents and complications are to be reduced. Besides these problems of technique there are others needing consideration, such as urinary sepsis. Some times varying degrees of pyelonephritis or infected hydronephrosis are present before operation and experience shows that such conditions are often favourable rather than otherwise because they favour immunity. The surgeon must needs consider not only his surgery but the possibility of raising the patient's resistance to it.

RESPIRATORY EFFICIENCY

WORKERS in many centres continue the search for an easy way of expressing the degree of efficiency or failure of the respiratory apparatus. Kaltreider and McCann⁵ report investigations on patients with chronic pulmonary disease comprising estimates of the ventilation respiratory rate tidal volume oxygen consumption and carbon dioxide production during a standard form of exercise in 20 normal subjects and in 28 patients with cardiorespiratory abnormalities. They also correlated their results with blood examinations and certain measurements of the chest. From these they conclude that the amount of dyspnoea is proportional to the expression $\frac{\text{total ventilation}}{\text{vital capacity}}$. They find that dyspnoea is experienced when this value is greater than 51 and that excess of this figure at low levels of work is an indication of pathological dyspnoea. The maximum minute ventilation that can be maintained for 1½ minutes is only roughly proportional to the vital capacity in normal subjects, but in chronic pulmonary disease the relation is closer. In their examination of other suggested tests for respiratory efficiency Kaltreider and McCann make certain valuable criticisms as for example, that the ventilation equivalent for oxygen (the amount of ventilation required per 100 c.c. of oxygen absorbed) suggested by Knipping Lewis and Nonce⁶ is not a good index of the degree of dyspnoea since it varies from person to person. The pulmonary reserve on the other hand is held to be a useful measure of the tendency to dyspnoea. Normal subjects can increase their resting minute volume about ninefold but patients disabled by pulmonary fibrosis and emphysema could often increase their ventilation only to about 60 per cent of the maximum minute ventilation on moderate exertion. The basis of the investigations has been the results obtained with subjects harnessed to a closed spirometer and in

⁶ p. 73.

two other papers: Lessen, Courmand, and Richards, offer damaging comments on certain of the measurements made of the respiratory gases in a closed breathing circuit. They show, for example, that when a normal person breathes for several minutes in a small closed circuit in which the oxygen concentration is steadily decreasing, a state of equilibrium is reached and maintained in which the concentration of the nitrogen expired is less than that of the nitrogen inspired. This is due to the progressive increase in inspired nitrogen concentration with each breath, to mixing of inspired air in the lungs with air previously inhaled, and to the exhalation of mixed samples. In the determination of residual air volumes by quiet breathing, in a closed circuit apparatus, use of alveolar air samples, obtained before and at the end of the breathing period, enables a correction to be made for the inequality of concentrations of inert gases through the system. This correction may amount to several hundred cubic centimetres in normal subjects. In patients with emphysema, with a poor distribution of tidal air and hypoventilation through a large part of the pulmonary air spaces, the errors may be even greater if the residual lung volumes are determined by methods of quiet breathing in a closed circuit. This fallacy of what these authors call "nitrogen lag" is one demanding serious attention since it may well prove to be one of the reasons why similar, but not exactly the same, spirometric experiments in different centres seem to give widely different results.

TUMOURS OF THE HAND

THE swellings other than acute infections that may arise in the hand are discussed by M. L. Mason³ (Chicago) with reference to origin and prognosis after removal. Ganglia he regards as being probably due to a gelatinous degeneration in the fibrous sheaths of the tendons or joint capsules, and not to synovial herniation as was previously held. Epidermoid cysts are attributed for the most part to implantation of epithelial cells, while a few may develop from congenital inclusions. Xanthoma is a tumour peculiar to the extremities, whose origin is not settled. It occurs as a firm slowly growing nodular mass, most often on the volar surface of the thumb or finger. The tumour is made up of lobules of yellow, orange, brown, and grey tissue, bound together by septa, and surrounded by a thin capsule. Microscopically it is seen to be composed of giant cells, large round cells, spindle cells, and foamy cells, it does not recur after complete removal. Fibromas and lipomas in the hand behave as they do elsewhere in the body. An interesting tumour is a telangiectatic granuloma, which follows infection in an abrasion. It bleeds freely, and recurs if not completely excised. Subungual melanoma and carcinoma are described, likewise carcinoma arising in an irritative lesion as after burns thermal and radiological, or chemical irritants. The prognosis of these is bad. Chondromata are common in the metacarpals and phalanges. Angiomata of various types occur in the hand. A tumour of recent recognition is called a glomus tumour, arising under the nail bed and sometimes elsewhere in the hand. It is said to be developed from the neurovascular arterial glomus of Masson,⁴ and is made up of blood vessels with thickened walls the media being replaced with epithelial cells, smooth muscle-fibres and innervated and unmyelinated nerve-

fibres. When this tumour is removed complete it does not recur.

Such detailed studies of regional surgery provide a useful pathological background for guidance in treatment.

CANCER OF THE LUNG

THE faint ray of hope that has flickered into the prognosis of carcinoma of the lung made it a suitable subject for the Silvanus Thompson lecture delivered at the British Institute of Radiology's congress last December. This lecture, which we summarised at the time, appears in full in the March issue of the *British Journal of Radiology*. The lecturer was Dr. A. C. Christie of Washington, and under the head of diagnosis he makes it very clear that earlier recognition is essential if treatment is to have a chance of success in more than a minute proportion of cases. When a patient of 40 or over complains of persistent cough with a small amount of sputum, sometimes blood stained and accompanied by moderate dyspnoea and pain, the suspicion of carcinoma should at once be raised. Physical signs are of little value and in reaching a diagnosis there must be careful correlation of information obtained by various means of which the most important are radiological and bronchoscopic. Once recognised, there is now a possibility of complete eradication of the growth and for this purpose total pneumonectomy is tending to take the place of lobectomy. Although it is at present applicable only in a small proportion of cases, the fact that any cures are possible should stimulate interest in early diagnosis to such an extent that these operable cases cease to be such rare exceptions. Radiation therapy has on the whole been disappointing in lung cancer, and it must be admitted that highly differentiated tumours in this region are almost completely radioresistant. With less differentiated tumours Dr. Christie considers the results more encouraging, especially when after careful localisation of the tumour, it is irradiated through several relatively small portals.

A CONFLICT OF PHILOSOPHIES

A LITTLE book¹ written with obviously sincere moral and religious convictions attacks what have been called, and perhaps properly, the "pretensions" of science in the philosophical and moral fields. In particular it attacks, on the one hand, the crude materialism implied if not expressed in many popular biological writings, and, on the other, the somewhat patronising attitude taken towards theology in modern books of cosmology and physics. One can understand the irritation aroused by this attitude in persons of a theological turn of mind whose humanistic background stretches beyond Heisenberg and Einstein to Spinoza and Jonathan Edwards. It is not unreasonable to regard the "indeterminacy principle" as a device of the physicist to get himself out of an awkward situation of his own making. Stepping stones have, before now, in science, been mistaken for foundation stones. The modern philosopher physicist might well feel some misgivings that illustrations from "Alice in Wonderland" come so glibly from his tongue. Even "free will" theologians of the sterner sort will hardly appreciate concessions that might equally be given as an excuse

¹ *The Philosophy of Religion versus The Philosophy of Science: An exposure of the worthlessness and absurdity of some conventional conclusions of modern science.* By Albert Eagle, lecturer in mathematics in the Victoria University of Manchester. Printed for private circulation and obtainable through all book sellers from Simpkin Marshall Ltd. 1935. Pp. 3.2. 5s.

for believing in any nonsense Mr Eagle is a trained mathematician and physicist and as such is obviously more at home in physics than in biology psychology or economics His attack on the relativity theory though it could no doubt be parried by an expert relativist is at least a pungent statement of the reactions of the ordinary man to the theory The main fault in this book is that the author attacks too much and too wildly and the reader becomes bewildered by his digressions through relativity and indeterminacy evolution and embryology psychology capitalism communism and the rest A philosopher must not be blamed for exercising his proper function as a critic of universal knowledge

but it needs happy moments for this skill and it is hardly work for the amateur Mr Eagle does however succeed in reminding us how many slipshod philosophical notions reach the ordinary reader in the form of asides in popular scientific writings This is difficult to avoid as the ordinary reader craves for general and sensational ideas and a sop must be thrown to him from time to time How far he is misled and how far it matters if he is are nice problems in the ethics of popular education He at least gets plenty of opportunity of hearing both sides of the argument, even if the argument is a bad one and it is unlikely that Mr H C Wells's fervent materialism will do him any more harm than Sir Arthur Eddington's light-hearted theology In other respects he will be unquestionably the better for such books as *The Science of Life* or *The Nature of the Physical World* which after all were not primarily written to teach him philosophy but to reveal to him some of the wonders of modern discovery

A NATIONAL FOOD POLICY

IN his broadcast last week the Minister of Health described the report of the Advisory Committee on Nutrition as the most valuable document on the subject yet issued and went on to set out the action he had already taken on it. He had he said that day communicated with all the maternity and child welfare authorities in the country asking them to review their arrangements for the supply of milk and other protective foods to mothers and young children. He deprecated the time limits placed on the supply of milk to expectant mothers and young children and suggested as a simple criterion the supply of sufficient milk or other food whenever the provision is necessary for the maintenance of the health of the mother or young child. He had asked local authorities to review the scales of income at present in force and to frame them in such a way as not to render it difficult for mothers to take advantage of the authorities' arrangements. Wherever possible the milk supply should be efficiently pasteurised and where this was not practicable the medical officer of health should approve the source and quality of the milk supply. He regretted the abandonment in various places of the organised system of supplying meals because of the difficulty in securing the attendance of sufficient mothers or young children and expressed a hope that the successful solution of the difficulty in certain large towns would be more widely followed. The new Act raising the block grants to local authorities and redistributing the grants so as to give a larger share to authorities who need was greatest should he thought, help to do away with local hesitation on grounds of financial stringency. Existing services deserved to be more widely known and he emphasised the share which the Ministry is taking in the autumn campaign to make the services better known and more fully

availed of. Finally he offered to discuss with representatives or officers of the local authority any difficulties in the way of a fuller realisation of the committee's recommendations.

WHAT IS OSTEOPATHY?

OSTEOPATHY began as and still is, an American cult. The founder of the faith Andrew Taylor Still was a remarkable man born in Virginia in 1828 and in 1874 the recipient according to his own account of a divine revelation of the true science of healing which he called osteopathy. What is osteopathy? Two doctors Charles Hill and H. A. Clegg have tried to answer this and relevant questions in a most readable book.¹ The authors are perhaps biased: they are doctors. Yet seeing that osteopathy deals with human disease and doctors are the only class in the community who can lay claim to having studied the subject scientifically that is no drawback and the fact that neither of the authors is engaged in medical practice ensures that their bias if it exists is not due to fear of direct professional rivalry. Their positions in the British Medical Association gave them a broad outlook on medicine and a benevolently critical attitude towards their brethren and in addition to a scientific training, they have developed a more than usually wide knowledge of the public and legal aspects of the healing art. It is not their fault that the reader will find a certain amount of confusion when he comes to the part of the book where they try to give a description of the cult: for Hill and Clegg are in the same predicament as an artist trying to produce a picture of a versatile chameleon: the beast changes colour while you look at it. In the history of disease there has been a progressive unfolding of the truth and even a revolutionary discovery in connexion with a particular disease is found sooner or later to harmonise with such earlier knowledge as existed. But osteopathy like the chameleon appears to change colour for protective reasons. Still believed that all disease could be ascribed to displacements of the spine ribs or hips. One would imagine that he would have hailed the advent of X rays with shouts of joy. Not a bit of it: no concerted attempt was made to employ the new diagnostic weapon and when it was found that osteopathic displacements could not be demonstrated radiographically and that easily demonstrable displacements of the spine and hips did not lead to other more remote diseases as the osteopaths taught the osteopathic lesion was born something much more subtle and elusive to replace the discredited displacement. It is a remarkable and instructive fact that this nebulous lesion found its way recently into the august session of our House of Lords. A Bill for the registration of osteopaths was introduced in 1935 and after attaining a second reading was referred to a Select Committee. Although the subsequent investigation was expensive and time consuming the resulting exposure of the osteopaths has done nothing but good. Dr Hill and Dr Clegg allow the committee a report to speak for itself: it shows condemnation. This for example: The only existing establishment in this country for the education and examination of osteopaths was exposed in the course of evidence before us as being of negligible importance inefficient for its purpose and above all in thoroughly dishonest hands. Throughout the book, indeed the evidence has been

¹ *What is Osteopathy?* by Dr Charles Hill and Dr H. A. Clegg. London: J. A. H. & Sons, 1937. Pp. 217. 1s. 6d.

arranged with great precision, and the whole story is told clearly and with engaging good humour.

A point remains for consideration. The fact that osteopathy reached the House of Lords was due to one thing—certain noble lords had been cured by osteopaths, where, presumably, the doctors had failed. This side of the question is examined, but one is left with the impression that manipulation of the spine (which in certain cases that drift to the osteopath cannot fail to do good) as well as of other joints is being regularly employed in suitable cases by members of the medical profession. Yet too often still one meets a patient who visited the bone setter or the osteopath after one or more doctors had failed to relieve him, and who was cured. This is not the place to discuss the teaching of manipulative surgery (perhaps the authors considered it outside the scope of their book), but this important subject certainly has a claim to more attention from medical students than, for various reasons, it now receives.

A DIRECTORY OF LONDON MUNICIPAL HOSPITALS

THE county of London having settled down to another three years of hospital administration undisturbed by thoughts of election, it is useful to have for reference a handbook¹ prepared by its hospitals and medical services committee. This committee is responsible for 65 general and special hospitals, a small pox receiving station, and 9 institutions containing at the present time beds for sick, healthy, and infirm inmates. The hospitals are classified as 27 general, 1 for the chronic sick, 15 infectious, 6 children's (sick and convalescent), 10 tuberculosis (including 4 for children only), 2 adult convalescent, 2 epileptic, 1 for ophthalmia neonatorum and vulvo vaginitis in children, and 1 for maternity cases associated with venereal disease. They contain some 38,500 beds, and the handbook gives concise information about them all under six headings, including an admirable hospital map of the county. Primarily the information is for the use of the managing committees, whose names and time of meeting are set out for each hospital, but there is a much wider circle which will welcome such a conspectus of the hospitals as a whole, with precise information about access, number of beds, particular kind of work done with alterations in progress or proposed, and the names and qualifications of heads of departments. On p. 90 of the handbook is an imposing list of the special units at the L.C.C. general hospitals of which further details will be found on p. 893 of our present issue.

ROCKEFELLER TRAVELLING FELLOWSHIPS

THE Medical Research Council announce that they have been entrusted by the Rockefeller Foundation of New York with £3000 annually, for three years in the first instance, for the award of travelling fellowships in medicine to candidates in the United Kingdom. This generous benefaction renews an arrangement which had been highly successful during an earlier period but which had latterly been interrupted during a revision of the Foundation's general policy. These Rockefeller fellowships are intended for graduates who have had some training in research work in clinical medicine or surgery or in some other branch of medical science, and are likely to profit by a period of work at a chosen centre

in the United States or elsewhere abroad before taking up positions for higher teaching or research in this country. Five or six fellowships will be available annually, and applications for the academic year 1937-38 will be invited in May. It is of interest to recall an analysis which was made, at the end of the previous ten year period, of the positions occupied by the 70 men and women who had completed their tenure of Rockefeller fellowships awarded by the Council. This showed that 12 were professors in universities, that 36 others occupied whole time positions for teaching and research, and that a further 16 held part-time appointments of the same kind.

FOOD AND EXERCISE

MANY people little disposed to listen to discussion of the principles governing nutrition or the best means of promoting physical culture take a lively interest in talk of food and exercise. Lord Horder was wise, therefore, in using concrete example and homely simile in a survey¹ introductory to a series entitled "Towards National Health" to be broadcast on Monday evenings during April, May, and June. Proper food, decent shelter, ample fresh air, a chance of doing work, a reasonable amount of leisure, and room for play—these, Lord Horder declared, are the means of health, and governments, central and local, can see to it that no section of the community lacks them. He dismissed the man who talks about the "secrets of good health" as either a crank or one who has something to sell, and showed how easily science can be prostituted to business ends. On the other hand, health is more than a balanced resistance to stresses. It implies the possession of some kind of purpose or passion, be it a lofty one or a low one. Lord Horder's conviction of the need for fostering zest for life if health is to be maintained led him to plead for exercise without exercise, though he does not minimise the value of sergeants and instructors in correcting faults of posture or gait. Just as natural and appetising foods are better for us than artificial and doctored foods, so, he holds, natural and enjoyable forms of exercise are better for us in every way than drill and physical jerks.

Future talks will be concerned with various aspects of nutrition and on May 24th they will be linked to a second part of the series by an account of the relation of physical culture to nutrition and to other aspects of national health.

¹ *The Listener* April 7th 1937 p. 655

UNIVERSITY COLLEGE HOSPITAL, LONDON.—It was announced at the annual meeting of governors of this hospital that all the new extensions were in full working order and almost all the pay beds occupied. The centenary appeal made in 1935 for £300,000 has now reached £102,839. The number of patients is increasing and general accounts show a deficit of over £5000, which will probably be increased by the burden of interest charged in connexion with the private patients' wing. Special efforts are being made to facilitate the admission of emergency cases.

EASTBOURNE EAR, NOSE, AND THROAT HOSPITAL.—The Marquess of Hartington was elected president of this hospital at the annual meeting on March 24th, in succession to the late Sir John Maitland. Legacies and gifts strengthened the financial position during 1936, and as the number of patients was increasing year by year—706 in patients and 2178 out patients had been treated during the last twelve months—it was hinted that the governors were contemplating the erection of a hospital on two floors in a quieter neighbourhood.

PRINCIPLES OF MEDICAL STATISTICS

XV—GENERAL SUMMARY AND CONCLUSIONS*

In the preceding sections I have endeavoured to make clear to the non-mathematically inclined worker some of the technique that the statistician employs in presenting and in interpreting figures. The major part of that discussion has been directed to two basic problems:—

(1) The *significance* or *reliability* in the narrow sense, of a difference which has been observed between two sets of figures—be those figures averages, measures of variability, proportions or distributions over a series of groups; and

(2) The *inferences* that can be drawn from a difference which we are satisfied is not likely to be due to chance.

A Secure Foundation for Argument

The discussion of the first problem led to the development of tests of significance—the standard errors of individual values, the standard errors of the differences between values, and the χ^2 test. The object of such tests is to prevent arguments being built up on a foundation that is insecure owing to the inevitable presence of sampling errors. Medical literature is full of instances of the neglect of this elementary precaution. Illustration is hardly necessary but I may perhaps give a quotation from an article published while I was preparing this section for the press: a mere list of the treatments which have been tried in thrombo-angitis obliterans would be of formidable length and there is little point in mentioning many of them—they have only too often fallen by the way after an introduction more optimistic than warranted by results (*Lancet* 1937 i 551). This general summary may well be written round that problem of clinical trials.

In general worker A who is at least careful enough to observe a control group reports after a short series of trials that a particular method of treatment gives him a greater proportion of successes than he secures with patients not given that treatment and that therefore this treatment should be adopted. Worker B sceptically or enthusiastically applies the same treatment to similar types of patients and has to report no such advantage. The application of the simple probability tests previously set out would have (or should have) convinced A that though his treatment may be valuable the result that he obtained might quite likely have been due to chance. He would consequently have been more guarded in his conclusions and stressed the limitations of his data.

If however the test satisfied worker A that the difference in reaction that he observed between his two groups was not likely to be due to chance then there comes the second and usually much more difficult problem. Were his two groups of patients really equivalent in all relevant characteristics except in their differentiation by mode of treatment? This question immediately emphasises the importance of the initial planning of clinical trials with some new treatment or procedure a point which was discussed in the first of these articles. The simple probability tests are not rules merely to be applied blindly at the end of an experiment whether that

* In sections IV and V I discuss the meaning and use of the standard deviation and the coefficient of correlation. I have been a bit slow to show how in practice these two statistical values are calculated. I propose to do this in two further sections which will follow this concluding summary.

experiment be well or badly carried out. Certainly they can tell us in either case whether certain observed results are likely or not likely to be due to chance—equally certainly they can tell us nothing beyond that. But if the trials are well planned then we can with reason infer that the significant difference observed between the groups is more likely to be due to the specific treatment than to any other factor for such other factors are likely to be equally present in both groups in the well planned test. If the trials are badly planned in the sense that the groups to be compared are allowed to differ in various important respects as well as in treatment then we can infer nothing whatever about the advantages of the specific treatment. The time to reach that very obvious conclusion is not at the end of the experiment when time and labour and money have been spent but before the experiment is embarked upon. To argue at the end of a badly planned experiment that the statistical method is not applicable is not reasonable. The statistical method (like any other method) must fail if it has to be applied to faulty material, but faulty material is often the product of a faulty experiment. Much thought in fact must be given to the devising of a good experiment of really effective clinical trials and the statistical aspect must be borne in mind from the start.

The Problems of Clinical Trials

With methods of treatment the main questions to be settled are usually these:—

(a) How can the patients be effectively allocated to the two groups which are to be compared—which we can refer to as the treated and control groups?

(b) What criterion or criteria can be used as evidence of the effects of treatment?

(c) On how many patients will the trials have to be made to give reliable results?

The answers to these questions will naturally vary with the particular case at issue but there may be some advantage in discussing them briefly in general.

(a) ALLOCATION TO GROUPS

By the allocation of patients to the two groups we want to ensure that these two groups are alike except in treatment. It was pointed out in the first section that this might be done with reasonably large numbers, by a random division of the patients, the first being given treatment A, the second being orthodoxly treated and serving as a control, the third being given treatment A, the fourth serving as control and so on, no departure from this rule being allowed. It was also pointed out that this method could be elaborated the groups being made equal in such well defined characteristics as age and sex and then randomly composed in other respects (and of course more than one form of treatment could be brought in). While the treatment to be tested has only an empirical basis—as it must have before it has been adequately tried out—there can be no serious moral objection to this procedure though practical difficulties of administration may well arise. On the other hand once there is evidence that one treatment gives better results than another (even though the evidence is slender) the moral problem becomes acute. One cannot treat human beings like laboratory animals and to withhold from a patient a treatment which is likely to benefit him is impossible. All the more important therefore is it to secure reliable evidence of the effects of a form of treatment before that

position arises. In the early days of a new treatment there are also likely to be some workers who regard it favourably, and others who distrust it. If a random division of patients is objected to, or is administratively impossible, it should be possible at this stage to make comparisons between similar types of patients to whom worker A is giving the treatment and worker B is not. For example, in the treatment of pulmonary tuberculosis by collapse therapy there are physicians who now believe that an artificial pneumothorax should be induced at an early stage, there must have been, and no doubt still are, many patients of similar types to whom that treatment has not been applied, who would serve as an effective standard of comparison. The difficulty is that usually any one worker's field of observation is too limited to give a convincing result, while a prolonged period of observation of each patient is also a necessity and difficult to secure. Organisation is required so that patients may be classified on a uniform system, and the results collated and judged by identical criteria. In the long run it is probable that useless forms of treatment will be discarded and the good will survive, but it may be an unfortunately long run which carefully controlled trials would have effectively shortened.

The advantage of recording limited data—Even the smallest amount of data has its advantage, if collected on some uniform system and clearly defined. In some instances it is only by the accumulation of such data that an answer to a problem can be reached. For example, there is some evidence that epidemics of milk-borne and water-borne enteric fever differ in the sex- and age-incidence of the persons attacked, the former attacking women and children—the larger consumers of milk—with proportionately greater frequency. The problem cannot be settled by the evidence from any one epidemic; it requires the accumulation of data from a series of epidemics of the two types. The field of observation of any one worker is insufficient, but if uniform data of the sex and age of patients are systematically collected and published reliable evidence will eventually be reached.

The problem of classification—In that particular instance the criteria for classification of patients, namely, age and sex, are simple, in grouping types of patients, given or not given a specific form of treatment, the task may be very much more difficult. No purely objective criteria may be available and subjective factors, variable from one worker to another, may enter in—for instance in classifying patients with cancer or pulmonary tuberculosis to the stage of disease. Can any system in each case be devised which with any worker ensures that like is being put with like, at least in broad categories? It is often said that it cannot be done, that particular problems are not susceptible to statistical analysis because patients cannot be efficiently classified before and after treatment. It is true that there are sometimes very serious difficulties in making such objective classifications but these difficulties must be faced if the problem is important. Can a clear cut answer be reached in any other way to the fundamental questions "is this treatment of value, of how great a value, and with what types of patients?" In the large majority of cases it is difficult to see how it can. Even if the treatment is not of general value but of apparently great benefit in relatively rare isolated cases, satisfactory evidence of that must lie in statistics—viz., that such recoveries (however rare) do not occur with equal frequency amongst equivalent persons not given that treatment. Sooner or later the case is invariably based upon that

kind of evidence, but in the absence of planned trials it is often later rather than sooner. If it be maintained merely in general terms that a particular type of patient fares much better under such and such a form of treatment, then two queries arise. If the patient can be thus defined as of this particular type why cannot he be classified and compared with the patients of similar type not specifically treated? To reach the conclusion that he has benefited from treatment he must have been compared at least mentally with his untreated prototype, and the conclusion is itself based upon statistical though unrecorded evidence. The difficulty does not seem to lie, in that case, in classifying (for the clinician has done that in drawing his conclusion) but rather in the small field of observation of any one worker and in the lack of organised trials in the earlier days of a form of treatment. It may of course be said with truth that no two patients are alike in all respects, but if that is a logical objection to classifications it is equally a logical objection to treating any patient on the basis of past experience. In medical statistics, moreover, we are not usually comparing the reactions of individuals but of broadly similar groups of individuals, and in comparing randomly chosen groups, or groups representative of a type, we can reasonably presume, if the groups are fairly large, that the distribution of unknown characters which may influence the issue is likely to be equivalent.

(b) ASSESSMENT OF THE RESULTS OF TREATMENT

The second query that arises from our general statement is *how much better* do the patients fare under the particular form of treatment? How can the advantage be qualitatively or quantitatively assessed? For that purpose the criterion of success or failure must be defined, and clearly the more objective it can be made the better it will be. The criterion must, of course, vary with the problem. It is useless to use the survival rate as an index with a disease that has an extremely low fatality rate. Speed of recovery may be an appropriate test in one case, incidence of complications in another, absence of remission in a third, structural change in yet another, and so on. The choice of criterion and the way in which it is to be measured or defined are inherent in the question at issue and an essential part of the planning of the experiment, the clinical trials, or whatever is under discussion. The way in which it is to be recorded, the means of securing uniformity if different workers are involved, and the steps to be taken to avoid the omission of necessary items of information, must all enter into this plan in its initial stages. Team work is often requisite and in that team I suggest (at the risk of being accused of over-emphasising the importance of my own subject) the medical statistician ought to be represented. His inclusion should have two advantages. He should be able to advise on the statistical aspects of the inquiry at its inception, and secondly, and equally important, he will learn at the start the details of the problem, the difficulties of solving it, and the factors that may complicate it. If his task is only to come in at the end, merely to make a technical analysis, he may be faced not only with material that is not capable of answering the questions posed but also with material which he may imperfectly understand, having had no previous association with it, and therefore be liable to misinterpret.

(c) THE NUMBERS REQUIRED

Finally a question very frequently put to the statistician relates to the size of the sample that is

necessary to give a reliable result. To that there is usually no simple answer. If two groups are to be compared a treated and a control group then the size of the sample necessary to 'prove the case' must depend upon the magnitude of the difference that ensues.

If to take a hypothetical example the fatality rate (or any other selected measure) is 40 per cent in the control group and 20 per cent in the treated group then by the ordinary test of significance of the difference between two proportions, that difference would be more than is likely to occur by chance with 42 patients in each group (taking twice the standard error as the level). In other words with those fatality rates we should have to take at least 42 patients in each group to feel at all confident in our results. If there were 50 patients in each group and 20 died in the control group and 10 in the specially treated group that difference is (on the criterion of significance adopted) more than would be likely to occur by chance. If on the other hand the improvement was a reduction of the fatality rate from 40 to 30 per cent we should need at least 182 patients in each group. If we had 200 in each group and 80 died in the one and 60 in the other that difference is more than would be likely to occur by chance. Finally if the fatality rate was only 4 per cent in the control group and 2 per cent in the treated group we should require as many as 600 patients in each group to be able to dismiss chance as a likely explanation. With that number in each group there would be 24 and 12 deaths and a difference of this order on smaller numbers might well be due to chance. (In such a case the fatality-rate of course might not be the best measure of the advantages of the treatment.)

The determination of the numbers required is based it will be noted, upon the difference observed between the groups. In practice we often do not know what that difference is likely to be until at least some trials have been made. There can be no answer given in advance to the question how many observations must be made. Unless there is some indication from past experience as to the kind of difference that may result, or unless we can argue on a priori grounds we must confess ignorance of the numbers required to give a convincing result.

Common Sense and Figures

Apart from these problems of the errors of sampling much of my discussion of the interpretation of figures has centred it will have been noted not so much on technical methods of analysis but on the application of common sense to figures and on elementary rules of logic. The common errors discussed in previous sections are not due to an absence of knowledge of specialised statistical methods or of mathematical training but usually to the tendency of workers to accept figures at their face value without considering closely the various factors influencing them—without asking themselves at every turn what is at the back of those figures? what factors may be responsible for this value? in what possible ways could these differences have arisen? That is constantly the crux of the matter. Group A is compared with Group B and a difference in some characteristic is observed. It is known that Group A differed from Group B in one particular way—e.g. in treatment. It is therefore concluded too readily that the difference observed is the result of the treatment. To reject that conclusion in the absence of a full discussion of the data is not merely an example of armchair criticism or of the unbounded scepticism of the statistician. Where as in all statistical work our results may be due to more than one influence there can be no excuse for ignoring that fact. And

it has been said with truth that the more anxious we are to prove that a difference between groups is the result of some particular action we have taken or observed the more exhaustive should be our search for an alternative and equally reasonable explanation of how that difference has arisen.

It is also clearly necessary to avoid the reaction to statistics which leads an author to give only the simplest statement of his figures on the grounds that they are dull matters to be passed over as rapidly as possible. They may be dull—often the fault lies in the author rather than in his data—but if they are cogent to the thesis that is being argued they must inevitably be discussed fully by the author and considered carefully by the reader. If they are not cogent then there is no case for producing them at all. In both clinical and preventive medicine and in much laboratory work we cannot escape from the conclusion that they are frequently cogent that many of the problems we wish to solve are statistical and that there is no way of dealing with them except by the statistical method.

A B H

AN ORTHOPÆDIC NURSING CERTIFICATE

THERE are at the present time in this country some thirty orthopaedic hospitals most of which issue certificates of proficiency to their nursing staff on completion of their training. These certificates lack uniformity and offer no accepted standard when applications for other posts are being considered. The Central Council for the Care of Cripples which since its inauguration in 1920 has acted as a coordinating body in matters concerning the welfare of cripples now proposes an orthopaedic nursing certificate based on a uniform syllabus. In consultation with the principal orthopaedic hospitals a scheme for such a certificate has been drawn up and the rules and syllabus have been issued in pamphlet form¹ by the Council. The certificate will be awarded as the result of tests held at the end of the first and second years of training respectively but probationer nurses who have passed the preliminary State examination will be exempt from the earlier test. The first which includes anatomy physiology hygiene and practical nursing both written and oral will be taken at the training hospital in May or November. The second test on orthopaedic conditions and their nursing will be taken partly at the hospital but for the practical and oral portion examinees will generally be asked to attend at a centre—London Bristol Newcastle or Birmingham—again in May or November. General State registered nurses will be allowed to sit for the final examination at the end of one year's training. The entrance fee will be 10s. 6d. for the first test and one guinea for the second. There are five orthopaedic surgeons on the executive committee of the Central Council one of whom Mr L. S. Evans has acted as chairman of the subcommittee which drew up the scheme. Dame Agnes Hunt who is president of the Council expresses the hope that every orthopaedic hospital which offers training to probationers will adopt the certificate so that its possession may be generally accepted as evidence of sound training in the elements of orthopaedic nursing. It is proposed to hold the first examination in November 1937.

MICRO-CHEMICAL METHODS OF
BLOOD ANALYSIS

By E J KING, M.A., Ph.D. Toronto

LONDON AT THE BRITISH POSTGRADUATE MEDICAL SCHOOL

G A D HASLEWOOD, M.Sc., Ph.D. Lond

ASSISTANT IN PATHOLOGICAL CHEMISTRY AT THE SCHOOL AND

G E DELORY, B.Sc. Lond

LABORATORY ASSISTANT IN PATHOLOGICAL CHEMISTRY
AT THE SCHOOL

THE methods of blood analysis here described have proved their usefulness in research and routine laboratory work. Some of the methods are modifications of published procedures, while others are new

A—PROCEDURES FOR WHOLE BLOOD

Micro chemical methods of blood analysis are particularly useful in investigations which require the taking of frequent samples of blood. Determinations on capillary blood, as compared with venous blood, are less inconvenient to the patient, who usually objects to numerous and elaborate veni punctures, and are less laborious for the investigator. A puncturing apparatus or a Hagedorn needle, together with a supply of capillary blood pipettes, is much easier to keep and to use than a supply of sterilised syringes and needles.

The accuracy of the micro methods is usually beyond question, and biochemical methods carried out on small quantities of capillary blood have given at least as consistent and as accurate results as the larger scale procedures from which they usually sprang. The advantage of being able to omit any anti coagulant substance in the taking of the sample needs no comment. The sample can be measured in most capillary blood pipettes with a high degree of precision, and the possibility of obtaining abnormal proportions of cells and plasma when sampling an improperly mixed specimen of venous blood (a potent source of error not often appreciated) is avoided.

The level of some substances in arterial blood is different and of greater physiological significance than the level in venous blood. This is notably so in the case of glucose. Arterial blood glucose is best estimated in capillary blood, which gives the same value.

The micro methods described have been developed primarily for use with capillary blood, but they are of course applicable to samples of venous blood.

TAKING OF BLOOD

Blood may be taken from a puncture on the ear or finger, but the most convenient place to obtain capillary blood is probably from the thumb over the bed of the nail. The part is wiped clean with a little ether or spirit and a stab of 1 to 2 mm deep is made by means of a puncturing apparatus or Hagedorn needle. A piece of soft rubber tubing or of gauze is wrapped fairly tightly about the thumb above the knuckle. On flexing the thumb a free flow of blood is usually obtained. If the blood does not come easily the rubber is released and the hand shaken in a downwards direction. This operation will ensure an adequate amount of blood when the tourniquet is

replaced and the thumb flexed. The pipette is held horizontally with its point in the drop of blood issuing from the stab wound. The blood is allowed to run in exactly to the 0.2 c cm mark. The pipette is then wiped, and the blood allowed to run into a 15 c cm conical centrifuge tube containing water or isotonic sodium sulphate solution, and by alternate blowing and sucking the pipette is washed several times with the solution.

I—Estimation of Urea in Blood

Urea represents about 50 per cent of the non protein nitrogen of the blood. Normally there are between 20 and 40 mg of urea present per 100 c cm. High values are found in conditions associated with impaired renal function—particularly in chronic nephritis, but also in some cases of acute nephritis, prostatic obstruction, cardiac failure, &c.*

PRINCIPLE

The sample of blood is digested with urease, and the urea thus converted into ammonia. After removal of proteins, the colour produced by the ammonia with Nessler's reagent is compared colorimetrically with the colour produced under the same conditions with a standard ammonium chloride solution.

Direct nesslerisation does not lead to the production of cloudiness in the case of protein free filtrates from unlaked blood. This is due to the fact that the sulphhydryl substances glutathione and ergothione, which produce turbidities with Nessler's reagent because of the insolubility of their mercury salts, are confined to the cells and do not appear in the filtrate, as is the case with filtrates of laked blood. Filtrates of unlaked blood have the further advantage that no ammonia is contributed to the determination through the action of the arginase of the red cell on the arginine contained in most commercial preparations of urease (see Addis 1928). The use of zinc hydroxide as deproteinising reagent eliminates a small amount of turbidity producing substance contributed by most preparations of urease.

METHOD

0.2 c cm of blood is added to a centrifuge tube containing 3.2 c cm of isotonic sodium sulphate solution.

A "knife point" (about 20 mg) of Jack Bean meal is added, and the whole stoppered with a rubber bung, mixed, and incubated at 37° C for 20 minutes. 0.3 c cm of zinc sulphate solution and 0.3 c cm of 0.5 N sodium hydroxide are added to precipitate the proteins, and the mixture is centrifuged. 2 c cm of the supernatant fluid represent 0.1 c cm of blood.

2 c cm of the clear supernatant are treated with 5 c cm of water and 1 c cm of Nessler's reagent. The solution is compared in a colorimeter† with a "high" or "low" standard made up with 2 c cm or 5 c cm of the standard ammonium chloride solution (0.01 mg of nitrogen per c cm), 5 c cm

* No attempt is made to give a complete statement of the amounts of the various substances present in diseased conditions nor to discuss their significance. Brief mention is made only of those clinical conditions in which abnormal values are most commonly encountered.

† A micro-colorimeter or micro attachments (cups and plungers) for an ordinary Duboscq are necessary for this and other colorimetric procedures. Micro-cups and plungers can now be obtained as interchangeable attachments for almost all the makes of colorimeters commonly in use.

or 2 c.cm respectively of water and 1 c.cm. of Nessler's reagent. The colorimetric comparison is facilitated by the use of a blue light filter (see section C)

CALCULATION

(1) Low standard

$$\text{Blood urea} \left\{ \begin{array}{l} - \frac{\text{Reading of standard}}{\text{Reading of test}} \times 0.02 \times \frac{100}{0.1} \times 14 \\ - \frac{\text{Reading of standard}}{\text{Reading of test}} \times 43.8 \end{array} \right.$$

(2) High standard

$$\text{Blood urea} \left\{ \begin{array}{l} - \frac{\text{Reading of standard}}{\text{Reading of test}} \times 0.05 \times \frac{100}{0.1} \times 2.14 \\ - \frac{\text{Reading of standard}}{\text{Reading of test}} \times 107 \end{array} \right.$$

N.B.—1 mg of nitrogen = 2.14 mg of urea.
mg/100 c.cm blood

SOLUTIONS

Nessler's reagent—As described in Peters and Van Slyke's *Quantitative Clinical Chemistry* Baltimore 1932, vol II p 532 and in Beaumont and Dodds's *Recent Advances in Medicine* 8th ed., London 1936 p 391

Standard ammonium chloride solution (containing 0.01 mg of nitrogen per c.cm.)—163 mg of pure ammonium chloride are weighed out and dissolved in water. The volume is made up to 100 c.cm. 25 c.cm of this solution with 10 c.cm. of N sulphuric acid are diluted to 1 litre with distilled water

Isotonic sodium sulphate—30 g of crystalline sodium sulphate ($\text{Na}_2\text{SO}_4 \cdot 10 \text{H}_2\text{O}$) are dissolved in water and made to 1 litre

Zinc sulphate—10 g of crystalline zinc sulphate ($\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$) are dissolved in water and made to 100 c.cm.

II.—Estimation of Non Protein Nitrogen

The non protein nitrogen containing substances of blood are urea (10–20 mg N), uric acid (1–2 mg N) creatinine (0.5–1 mg N) amino acid nitrogen (0.8 mg N) and substances such as glutathione and ergothioneine (5–10 mg N per 100 c.cm of blood). The normal range of non protein nitrogen (N.P.N.) is from 25–40 mg per 100 c.cm. Increased values are found in the conditions showing a high blood urea

PRINCIPLE

The proteins of laked blood or plasma are precipitated by trichloroacetic acid. Part of the filtrate is digested with sulphuric acid until all the nitrogen is converted into ammonium sulphate. The ammonium salt is estimated colorimetrically with Nessler's solution excess of which is used for the test in order to neutralise the sulphuric acid and give an alkaline medium.

METHOD

0.2 c.cm of blood (or plasma) is pipetted into 3.2 c.cm of water or isotonic sodium sulphate solution. Proteins are precipitated by the addition of 0.6 c.cm of trichloroacetic acid. The tube is stoppered and thoroughly shaken. After five minutes the mixture is filtered.

1 c.cm of the filtrate (≈ 0.05 c.cm of blood or plasma) is evaporated in a test tube with 0.5 c.cm. of 30 per cent sulphuric acid until the liquid turns dark and white acid fumes are evolved. The cooled liquid is then treated with 1 drop of hydrogen peroxide (30–100 vols.) to destroy any coloured products and boiled for 4 minutes. To the cooled solution are now added 5 c.cm of water and 3 c.cm of Nessler's solution. The colour produced is compared in the colorimeter with the low or high standard used in the determination of blood urea.

CALCULATION

(1) Low standard:

$$\text{N.P.N.} \left\{ \begin{array}{l} - \frac{\text{Reading of standard}}{\text{Reading of test}} \times 0.02 \times \frac{100}{0.05} \\ - \frac{\text{Reading of standard}}{\text{Reading of test}} \times 40 \end{array} \right.$$

(2) High standard

$$\text{N.P.N.} \left\{ \begin{array}{l} - \frac{\text{Reading of standard}}{\text{Reading of test}} \times 0.05 \times \frac{100}{0.05} \\ - \frac{\text{Reading of standard}}{\text{Reading of test}} \times 100 \end{array} \right.$$

In mg/100 c.cm of blood or plasma

SOLUTIONS

Nessler's reagent and ammonium chloride standard as described for urea (A I)

Trichloroacetic acid—25 g are dissolved in water and made to 100 c.cm

30 per cent sulphuric acid—30 c.cm. concentrated acid are allowed to run slowly and with shaking into about 60 c.cm of distilled water in a 100 c.cm volumetric flask. The mixture is cooled to room temperature made to the mark, and mixed

III.—Estimation of Uric Acid in Blood

Uric acid is normally present to the extent of 2–4 mg per 100 c.cm of blood. In gout and in certain conditions of renal impairment high values are found

PRINCIPLE

Blood in isotonic sodium sulphate solution is treated with a phosphotungstic acid reagent. This precipitates the proteins and on addition of sodium cyanide to the supernatant liquid the excess of phosphotungstic acid reagent produces a blue colour with uric acid present. The colour is compared with that given by a standard solution of uric acid. The blood must not be laked as interfering substances such as glutathione and ergothioneine would be liberated from the cells

METHOD

0.2 c.cm of capillary blood is pipetted into 3.2 c.cm. of isotonic sodium sulphate in a 15 c.cm centrifuge tube. 0.6 c.cm of Folin's (1934) uric acid reagent is added. The tube is stoppered its contents mixed gently by inversion and immediately centrifuged. 2 c.cm of the supernatant liquid (≈ 0.1 c.cm of blood) are treated with 1 c.cm. of sodium cyanide urea reagent. At the same time a mixture of 1 c.cm. of the uric acid blood standard (≈ 0.004 mg uric acid) 0.7 c.cm of distilled water and 0.3 c.cm of Folin's reagent is treated also with 1 c.cm of sodium cyanide-urea reagent. The two tubes are placed in a boiling water bath for 5 minutes cooled and the solutions compared colorimetrically

CALCULATION

$$\text{Uric acid} \left\{ \begin{array}{l} - \frac{\text{Reading of standard}}{\text{Reading of test}} \times 0.004 \times \frac{100}{0.1} \\ - \frac{\text{Reading of standard}}{\text{Reading of test}} \times 4 \end{array} \right.$$

mg/100 c.cm of blood.

SOLUTIONS

Isotonic sodium sulphate as under blood urea (A I)

Sodium cyanide urea reagent—5 g of sodium cyanide and 20 g of urea are dissolved in water and the volume made to 100 c.cm. The urea prevents clouding during the determination

Folin's (1934) uric acid reagent—(1) Preparation of molybdate free sodium tungstate a solution of 2.0 g of sodium tungstate in 500 c.cm. of water is treated with 5 N hydrochloric acid until neutral to litmus paper. The

solution is saturated with hydrogen sulphide, and allowed to stand 24 hours. It is then treated with 400 c cm of absolute alcohol added gradually with constant shaking. The mixture after standing for a further 24 hours, is filtered and the precipitate washed with 50 per cent alcohol and dissolved in 375 c cm of water. 0.5 c cm of bromine is added, and the mixture boiled gently until the excess bromine is dispelled. Sodium hydroxide solution (40 g per 100 c cm) is now added to the hot solution until the latter is alkaline to phenolphthalein. The cooled solution filtered if necessary, is treated with 200 c cm of absolute alcohol, and allowed to stand for 24 hours. The white crystals are filtered off and dried in a desiccator.

(2) Preparation of reagent. 100 g of molybdate free sodium tungstate are treated gradually with a solution of 30 c cm of "syrupy" phosphoric acid (89 per cent) in 150 c cm of water. The mixture is boiled gently under reflux for 1 hour, decolorised as above with a drop of bromine, cooled and diluted to 500 c cm.

Stock uric acid standard (Folin) ($\equiv 1$ mg per c cm) — 1 g of uric acid is placed in a 1 litre flask. 0.6 g of lithium carbonate is dissolved in 150 c cm of cold water. The carbonate solution, filtered if necessary and warmed to 60° C, is added to the flask containing the uric acid, which is warmed under the hot tap. The warm mixture is shaken for five minutes, cooled at once under the tap, and treated with 20 c cm of formalin (40 per cent solution of formaldehyde) and enough water to fill half the flask. A few drops of methyl orange are added, and then gradually with shaking, 25 c cm of N sulphuric acid. The solution should turn pink when 2–3 c cm of acid remain to be added. The mixture is now diluted to 1 litre, mixed and stored in the dark in a stoppered bottle, when it will keep almost indefinitely.

Uric acid "blood" standard ($\equiv 0.004$ mg per c cm) — 2 c cm of the above "stock" standard solution are diluted with water and 1 c cm of 40 per cent formalin to 500 c cm. This solution should be made up fortnightly.

IV—Creatinine in Blood

PRINCIPLE

Creatinine gives a red colour with alkaline solutions of picric acid (Jaffe's reaction). A similar colour is also given by blood (and plasma) filtrates. It is not certain that the colour in this case is due to creatinine, but the substance which may thus be estimated as blood "creatinine" is of some clinical importance. Calculated as "creatinine" the normal values are 1–2 mg per 100 c cm of blood. In advanced renal failure enhanced values may be found.

METHOD

0.2 c cm of blood is added to 1.4 c cm of isotonic sodium sulphate solution. 0.2 c cm of zinc sulphate solution and 0.2 c cm of 0.5 N sodium hydroxide are added and the tube is stoppered and shaken. The mixture is centrifuged, and 1 c cm of the clear supernatant fluid ($\equiv 0.1$ c cm of blood) is used as "test" solution (see Somogyi 1930).

For normal blood a "standard" solution is made by diluting 1 c cm of the creatinine "blood" standard described below, with 4 c cm of water. The "test" solution and 1 c cm ($\equiv 0.001$ mg of creatinine) of this "standard" solution are then treated at the same time with 0.5 c cm of freshly made alkaline picrate solution (see below). After not more than 15 minutes the solutions are compared in the colorimeter, using a blue green light filter, such as Ilford's spectrum blue green (see section C).

CALCULATION

$$\text{Blood creatinine} \cdot \left\{ \begin{array}{l} - \frac{\text{Reading of standard}}{\text{Reading of test}} \times 0.001 \times \frac{100}{0.1} \\ - \frac{\text{Reading of standard}}{\text{Reading of test}} \times 1.0 \end{array} \right. \\ \text{mg per 100 c cm blood}$$

In cases where a raised blood "creatinine" is found or expected, stronger "standards" may be made by using larger quantities of the "blood standard," and diluting these as before to 5 c cm with water. In general the calculation becomes —

$$\text{Blood creatinine} \cdot \left\{ \begin{array}{l} - \frac{\text{Reading of standard}}{\text{Reading of test}} \times C \times 0.001 \times \frac{100}{0.1} \end{array} \right.$$

where C is the number of c cm of "blood" standard used in the 5 c cm of "standard" solution.

Preparation of solutions — Isotonic sodium sulphate, 10 per cent zinc sulphate, and 0.5 N sodium hydroxide as under blood urea (A I).

Creatinine "stock" standard (containing 1 mg of creatinine per c cm) — 1.602 g of pure creatinine zinc chloride are dissolved in N/10 hydrochloric acid solution and the volume made up with the N/10 acid to 1 litre.

Creatinine "blood" standard (0.005 mg per c cm) — 5 c cm of the above "stock" standard are treated with 10 c cm of N/10 hydrochloric acid and the volume made up with water to 1 litre.

Alkaline picrate solution — Five parts (by volume) of a saturated aqueous solution of pure picric acid, containing about 15 g picric acid per litre are mixed with 1 part (by volume) of 10 per cent sodium hydroxide.

Note — The picric acid may be purified by recrystallisation from glacial acetic acid. It must be of such purity that when 10 c cm of a saturated aqueous solution are treated with 5 c cm of the 10 per cent hydroxide, the colour (determined in the colorimeter) of the alkaline mixture so formed is not more than twice as deep as that of the saturated picric acid solution.

V—Inorganic Phosphate

The blood of normal adult persons contains 2–3 mg per 100 c cm (expressed as P) of inorganic phosphate. In conditions involving an acidosis, such as is often found in nephritis, the amount present may be definitely raised. The amount of phosphate present in the blood of children, where bone formation is not yet complete, is at a higher level—usually of about 5 mg per 100 c cm. In rachitic conditions the figure is lowered.

PRINCIPLE

The inorganic phosphate of a deproteinised filtrate of the blood is coupled with molybdate, and the yellow phospho molybdate is reduced to give a blue substance. The amount of blue colour produced in the solution is directly proportional to the amount of phosphate present.

METHOD

0.2 c cm of whole blood or plasma is pipetted into 3.2 c cm of water or isotonic sodium sulphate and treated with 0.6 c cm of 25 per cent trichloroacetic acid. The mixture is shaken well, and after 5 minutes filtered through a small paper. 2 c cm of the clear filtrate ($\equiv 0.1$ c cm of blood or plasma) are treated at the same time as 2 c cm of the dilute standard phosphate solution ($\equiv 0.004$ mg P) with 0.3 c cm of the ammonium molybdate solution followed by 0.2 c cm of the reducing agent (ammonium naphtholsulphonic acid). The contents of the tubes are gently shaken between each addition, and the colours are read after 10 minutes in a colorimeter (King 1932).

CALCULATION

$$\text{Blood phosphate} \cdot \left\{ \begin{array}{l} - \frac{\text{Reading of standard}}{\text{Reading of test}} \times 0.004 \times \frac{100}{0.1} \\ - \frac{\text{Reading of standard}}{\text{Reading of test}} \times 4 \end{array} \right. \\ \text{mg P/100 c cm of blood}$$

SOLUTIONS

Trichloroacetic acid solution — As under non protein nitrogen (A II).

Ammonium molybdate — 5 g of ammonium molybdate are added to a mixture of 75 c cm distilled water and

15 c.cm. of concentrated sulphuric acid in a 100 c.cm. volumetric flask. The mixture is shaken until dissolution is complete and cooled to room temperature. The solution is then made up to 100 c.cm. and mixed.

Reducing agent—0.2 per cent. aminonaphtholsulphonic acid. 0.2 g. of the 1:2:4-acid 12 g. sodium metabisulphite and 2.4 g. crystalline sodium sulphite are dissolved by shaking with enough water to make 100 c.cm. If the solution does not filter clear it should be left overnight and filtered again. A fresh solution should be prepared every two weeks.

Standard phosphate—A stock solution is made by dissolving 2.194 g. of pure potassium dihydrogen phosphate (KH_2PO_4) in 500 c.cm. in water. This solution contains 1 mg. P per c.cm. A dilute standard solution is made by diluting 2 c.cm. of the stock solution to 1 litre with water. 1 c.cm. of this solution contains 0.002 mg. P. Both solutions should be kept saturated with chloroform to prevent any bacterial growth which might cause a loss of inorganic phosphate.

VI—Cholesterol in Blood

Total cholesterol in the blood of normal persons may be present in amounts varying from 120 to 230 mg. per 100 c.cm. The amounts present in blood may be raised in severe diabetic biliary obstruction and in some forms of nephritis (particularly the nephrotic type). Low values are found in severe anæmia.

The method recommended is that described in detail by Sackett (1925).

VII—Glucose

Harding's (1932, 1933) modification of the Schaffer-Hartmann method. This method gives true sugar values as opposed to total reducing substances when applied to filtrates of unclotted blood.

PRINCIPLE

The sugar in whole blood is a mixture of glucose present mainly in the plasma and nitrogenous reducing compounds (chiefly glutathione) in the corpuscles. It is possible to exclude the corpuscles by mixing the blood with isotonic sodium sulphate solution in which the corpuscles remain intact. A determination of the reducing power then becomes equivalent to an estimation of glucose alone. For normal (fasting) individuals values of 85–90 mg. per 100 c.cm. are found.

METHOD

0.2 c.cm. of blood is added to 3.2 c.cm. of isotonic sodium sulphate. After 4 minutes standing to allow diffusion from the cells 0.3 c.cm. of zinc sulphate solution and of 0.5 N sodium hydroxide are added. The mixture is shaken and then centrifuged.

2 c.cm. of the supernatant liquid (≈ 0.1 c.cm. of blood) are treated with 2 c.cm. of the mixed copper reagent in a wide (2 in.) test tube.

A blank is prepared with 2 c.cm. of distilled water and 2 c.cm. of reagent. Both tubes stoppered lightly with cotton wool are placed in a boiling water bath for exactly 10 minutes. They are then cooled at once under the tap. To each is added 2 c.cm. of 1 per cent. potassium iodide and 2 c.cm. of N sulphuric acid. After standing 1 minute the contents of each tube are titrated with $\frac{1}{200}$ sodium thiosulphate. One per cent. soluble starch (made up in water or better in saturated phenol red solution) is used as indicator. The titration figure of the test solution is subtracted from that of the blank.

† If the sugar determination cannot be made immediately it is advisable to keep the blood in an isotonic sodium sulphate containing fluoride in 1 M solution—see solution.

CALCULATION

1 c.cm. N/200 thiosulphate = 0.116 mg. glucose

The c.cm. of thiosulphate given by the difference between the blank and test titrations is equivalent to the amount of glucose present in the test. Hence—
c.cm. N/200 thiosulphate $\times$ 0.116 = mg. glucose in c.cm. filtrate (i.e. in 0.1 c.cm. blood)

And therefore—

$$\left. \begin{aligned} \text{c.cm. N/200 thiosulphate} \\ \times 0.116 \times \frac{100}{0.1} \end{aligned} \right\} = \text{mg. of glucose/100 c.cm. blood}$$

$$\text{i.e. c.cm. of N/200 thio} \left. \begin{aligned} \text{sulphate} \times 116 \end{aligned} \right\} = \text{mg. of glucose/100 c.cm. blood}$$

If the blood-sugar value thus obtained is greater than 400 mg./100 c.cm. the determination should be repeated using as test solution a mixture of 1 c.cm. of filtrate and 1 c.cm. of water. The result then obtained is multiplied by 2.

SOLUTIONS

Isotonic sodium sulphate containing fluoride and thymol to prevent glycolysis—100 mg. of sodium fluoride and 10 mg. of thymol are dissolved in 100 c.cm. of the 3 per cent. sodium sulphate 10 per cent. zinc sulphate and 0.5 N sodium hydroxide as for blood urea (A.I.).

Copper reagent—Solution A. 13 g. copper sulphate crystals are dissolved in water and the volume made up to 1 litre.

Solution B is made by dissolving: 24 g. Rochelle salt (sodium potassium tartrate) 40 g. anhydrous sodium carbonate 50 g. sodium bicarbonate 30.8 g. potassium oxalate and exactly 1.4 g. potassium iodate separately in the minimum quantities of water at room temperature. The solutions are then mixed and the volume made up to 1 litre.

The copper reagent is a freshly made mixture of exactly equal volumes of solutions A and B.

Note—Only purest analytical chemicals should be used in making up the above reagent. When preparing a fresh copper reagent it is advisable to check it against a solution of pure glucose.

B—PROCEDURES FOR PLASMA

I—Plasma Proteins

The total quantity of protein in blood plasma varies in normal individuals from approximately 6 to 8 g. per 100 c.cm. Plasma protein is divided into two main fractions, globulin and albumin. Globulin includes fibrinogen. Normally the approximate amounts of the proteins in plasma are albumin 3.4–4.0 g. per 100 c.cm. globulin (excluding fibrinogen) 1.5–3.0 g. per 100 c.cm. fibrinogen 0.2–0.4 g. per 100 c.cm. Where there is decrease of plasma protein—e.g. through proteinuria or malnutrition—the albumin is chiefly affected and there is often a reduction of the albumin globulin ratio (normally 1.3–4.0). A reduction of this kind is characteristic of nephrosis. An increase in the globulin especially fibrinogen may accompany inflammatory conditions.

PRINCIPLE

Oxalated plasma diluted with isotonic sodium chloride is used for estimation of total protein. Another portion of the diluted plasma is treated with calcium chloride and the fibrin clot removed. A further (fresh) sample of plasma is treated with saturated sodium sulphate solution which precipitates the globulin and the filtrate is used for estimation of albumin. For total protein and albumin the protein is precipitated with zinc sulphate and sodium hydroxide, the precipitates and the fibrin clot being then digested with sulphuric acid and hydrogen peroxide. The protein nitrogen is estimated

colorimetrically, as ammonium sulphate, with Nessler's solution. The nitrogen figures multiplied by 6.25 give the approximate protein values, which are expressed as grammes per 100 c cm of plasma.

METHOD

(A) *Total protein*—0.2 c cm of plasma (from oxalated blood) in a 10 c cm volumetric flask is diluted to 10 c cm with isotonic (0.9 g per 100 c cm) sodium chloride. 0.2 c cm of this solution ($\equiv 0.004$ c cm of plasma) is pipetted into 4 c cm of water in a Pyrex centrifuge tube. 0.1 c cm of zinc sulphate and 0.1 c cm of 0.5 N sodium hydroxide are added with mixing, and the precipitate is centrifuged down.

When the supernatant liquid has been carefully decanted, the inverted tube is drained on a filter paper. 0.5 c cm of 30 per cent sulphuric acid is added, together with a small piece of porous pot. The mixture is gently boiled until blackening occurs and white acid fumes appear. One drop of hydrogen peroxide (99–100 vols) is added to the cooled solution, and boiling continued for 4 minutes. To the cold colourless solution are added 5 c cm of water and 3 c cm of Nessler's solution. The colour is compared with a standard prepared from 5 c cm of the standard ammonium chloride solution (containing 0.01 mg of nitrogen per c cm), 2 c cm of water, and 1 c cm of Nessler's solution.

CALCULATION

$$\text{Total protein (A)} \cdot \left\{ \begin{array}{l} - \frac{\text{Reading of standard}}{\text{Reading of test}} > 0.05 \times \frac{100}{0.004} \times \frac{6.25}{1000} \\ - \frac{\text{Reading of standard}}{\text{Reading of test}} \times 1.25 \times 6.25 \end{array} \right.$$

* g / 100 c cm of plasma

(B) *Fibrin*—To another 5 c cm ($\equiv 0.1$ c cm of plasma) of the solution of plasma in isotonic sodium chloride, placed in a narrow tube, is added 0.1 c cm of calcium chloride solution. The mixture is kept at 37° C until clotting occurs. The fibrin is carefully collected on a thin glass rod, pressed to remove liquid, washed with water, and dropped into a test tube for digestion. This, and also the colorimetric estimation, is carried out exactly as in the case of total protein.

CALCULATION

$$\text{Fibrin (B)} \cdot \left\{ \begin{array}{l} - \frac{\text{Reading of standard}}{\text{Reading of test}} \times 0.05 \times \frac{100}{0.1} \times \frac{6.25}{1000} \\ - \frac{\text{Reading of standard}}{\text{Reading of test}} \times 0.05 \times 6.25 \end{array} \right.$$

* g / 100 c cm of plasma

(C) "*Albumin*"—0.2 c cm of plasma is placed in a 5 c cm volumetric flask. The volume is made up to 5 c cm with a saturated solution of sodium sulphate. The mixture is kept at 37° C for 3 hours and is then filtered through a fine filter paper. 0.2 c cm of the filtrate ($\equiv 0.008$ c cm of plasma) is placed in 4 c cm of water in a Pyrex centrifuge tube and the protein precipitated with zinc sulphate and sodium hydroxide, drained, digested, and estimated as ammonium sulphate exactly as in the case of total protein.

CALCULATION

$$\text{Albumin (C)} \cdot \left\{ \begin{array}{l} - \frac{\text{Reading of standard}}{\text{Reading of test}} \times 0.05 \times \frac{100}{0.008} \times \frac{6.25}{1000} \\ - \frac{\text{Reading of standard}}{\text{Reading of test}} \times 0.625 \times 6.25 \end{array} \right.$$

* g / 100 c cm of plasma

D = Total protein - fibrin + albumin
 Globulin = A - (B + C)

Note—A blue filter may be used with advantage in this colorimetric comparison (see section C).

SOLUTIONS

Thirty per cent sulphuric acid, Nessler's reagent, and standard ammonium chloride as for urea and non protein nitrogen (A, I and II).

Calcium chloride—2.5 g per 100 c cm in water.

Saturated sodium sulphate—22.2 g of anhydrous sodium sulphate (Na_2SO_4) dissolved in warm water and made to 100 c cm. The solution is kept at about 37° C.

II—Bilirubin

Normal blood contains small amounts of the yellow pigment bilirubin. These quantities may be greatly increased in various types of jaundice.

PRINCIPLE

The plasma is treated with diazotised sulphanilic acid, with the addition of ammonium sulphate and alcohol to precipitate the protein. The red colour produced was originally compared colorimetrically against a standard solution of bilirubin, treated with diazotised sulphanilic acid. This is, however, difficult to obtain pure, and various artificial "permanent standards" have been devised. The most satisfactory is that containing methyl red (o carboxy benzene azo dimethylaniline—2.9 mg per litre at pH 4.63) in sodium acetate buffer. The colour of this solution accurately matches the colour obtained when 0.1 mg of bilirubin is treated with the diazo reagent in a final volume of 25 c cm.

METHOD

1 c cm of plasma is treated in a centrifuge tube with 0.5 c cm of diazo reagent, 0.5 c cm of saturated ammonium sulphate, and finally 3 c cm of absolute ethyl alcohol. The mixture is stoppered, thoroughly mixed, allowed to stand for a few minutes, and filtered. Under these conditions the dilution of the plasma closely approximates to 1 in 4, allowance being made for the volume of the precipitate and for the change in volume when alcohol is added to water. The colour of the clear filtrate is compared with the standard mentioned above ($\equiv 0.1$ mg of bilirubin in a volume of 25 c cm) (Haslewood and King 1937).

CALCULATION

$$\text{Bilirubin} \cdot \left\{ \begin{array}{l} - \frac{\text{Reading of standard}}{\text{Reading of test}} \times 0.1 \times \frac{4}{25} \times \frac{100}{1} \\ - \frac{\text{Reading of standard}}{\text{Reading of test}} \times 1.6 \end{array} \right.$$

* mg / 100 c cm plasma

It is frequently found that brownish or purplish tints produced in the reaction make colorimetric comparison with the artificial standard difficult. These extraneous colours (probably due to traces of substances other than bilirubin which react with the diazo reagent) may be eliminated by the use of a coloured light filter (see section C).

The green filter (Ilford spectral green $\frac{1}{2}$ in diameter is an appropriate type) is placed over the eye piece of the colorimeter and the reading made against the artificial standard. The adjustment is then made in a green field whose two halves are of exactly the same quality of colour, and differ only in intensity. The reading is taken in the usual way.

SOLUTIONS

Stock standard methyl-red solution—0.29 g of pure methyl red is dissolved in glacial acetic acid and the volume made to 100 c cm.

§ There is no generally accepted range of normal values for blood bilirubin. Research in progress suggests that the normal values determined by this method fall within the range 0.1 to 1.3 mg per 100 c cm of plasma with the majority of the values within the limits 0.3 to 0.8 (Vaughan and Haslewood 1937). If the diazo reagent is carefully layered above the plasma and the tube allowed to stand for a few moments a positive direct reaction (if present) may be seen at the liquid junction.

Methyl red standard (20 mg per litre at pH 4.03)—1 c.c.m. of the above standard is placed in a litre flask together with 5 c.c.m. of glacial acetic acid. Water is added and 14.4 g. of crystallised sodium acetate are washed into the flask. When dissolution is complete the volume is made to 1 litre with water.

The diazo reagent—This is made by mixing two solutions A and B.

Solution A is made by dissolving 1 g. of sulphanilic acid in 250 c.c.m. of N hydrochloric acid and making the volume to 1 litre with water.

Solution B contains 0.5 g. of sodium nitrite in 100 c.c.m. of aqueous solution.

The diazo reagent mentioned above is made freshly before use by mixing 0.3 c.c.m. of solution B with 10 c.c.m. of solution A.

III—Plasma Phosphatase

PRINCIPLE

The estimation of phosphatase depends upon measuring the amount of hydrolysis which takes place when the enzyme is allowed to act on a suitable substrate—an ester of phosphoric acid (such as phenyl phosphate) under standard condition. The amount of phosphate or phenol so liberated may be taken as the measure of the amount of enzymic present. The phenol is more conveniently determined than the phosphate and three times as much phenol as phosphorus is set free. The hydrolysis is carried out at the optimum pH of 10 for 15 minutes. The results thus obtained agree very closely with those of the method of King and Armstrong (1934) of which this is a modification and with the method of Jenner and Kay (1932). The results are expressed in arbitrary units of phosphatase activity. By this method the blood of normal individuals contains 5–10 units per 100 c.c.m. of plasma. Great increases are found in cases of generalised bone disease and obstructive jaundice. Infective and toxic jaundices show smaller increases.

METHOD

Test—In a conical centrifuge tube are placed 4 c.c.m. of buffer substrate. The tube is allowed to remain in a water bath at 37°C for 5 minutes. Without removal of the tube from the bath exactly 0.2 c.c.m. of plasma (which must be cell free) is added and mixed. The stoppered tube is allowed to remain in the bath exactly 15 minutes. At the end of this time 1.8 c.c.m. of dilute phenol reagent are added and the mixture centrifuged or filtered.

Control—In another tube are placed 4 c.c.m. of buffer substrate, 0.2 c.c.m. of plasma and at once 1.8 c.c.m. of dilute phenol reagent are added and the mixture centrifuged or filtered.

4 c.c.m. of filtrate from the test and control solutions are pipetted into test tubes, 1 c.c.m. of 20 per cent. sodium carbonate is added and the tubes replaced in the water bath for 5 minutes to bring up the colour.

Comparison—The solutions are compared in the colorimeter with a standard made up at the same time by taking 4 c.c.m. of standard phenol-solution and reagent and 1 c.c.m. of 20 per cent. sodium carbonate. The tested solution is placed on the left hand side of the colorimeter and set at 30 mm. The standard is placed on the right hand side and the colours matched. The use of an orange or red filter will be found to increase the ease of colorimetric comparison particularly with weak solutions (see section C).

CALCULATION

The phosphatase activity of a plasma is expressed as units per 100 c.c.m. and is numerically equal to the mg. of phenol which would be set free from the phenyl

phosphate under the standard conditions by 100 c.c.m. of plasma. Thus:—

$$\frac{\text{mg phenol per 100 c.c.m. plasma in test}}{\text{mg phenol per 100 c.c.m. plasma in control}} = \frac{\text{Units of phosphatase per 100 c.c.m. plasma in test}}{\text{Units of phosphatase per 100 c.c.m. plasma in control}}$$

The number of mg phenol in 100 c.c.m. of plasma in the test and in the control is found by the equation:—

$$\frac{\text{Reading of standard} \times \text{strength of standard}}{\text{Reading of test}} = \frac{6 \times 100}{4 \times 100}$$

With the unknown solution set at 30 mm and the strength of standard = 0.04 mg thus equation can be written:—

$$\frac{\text{Reading of standard}}{30} \times 0.04 \times \frac{6 \times 100}{4 \times 100}$$

All figures in the above equation cancel out making it equal to Reading of Standard.

More simply then:—

$$\frac{\text{Units of phosphatase per 100 c.c.m. plasma in test}}{\text{Reading of standard against the test}} = \frac{\text{Reading of standard against the control}}{\text{Reading of standard against the control}}$$

SOLUTIONS

1 **Buffer substrate**—M/200 phenyl phosphate in M/20 sodium carbonate—M/20 bicarbonate buffer 1.09 g. di-sodium phenylphosphate 5.3 g. anhydrous sodium carbonate and 4.2 g. sodium bicarbonate are dissolved in water and made to 1 litre. The mixture is preserved in a well stoppered bottle with a few drops of chloroform and kept in the ice-chest when not in use.

2 **Phenol reagent of Folin and Ciocalteu**—As described in Peters and Van Slyke's "Quantitative Clinical Chemistry" vol. II p. 685 and Beaumont and Dodd's "Recent Advances in Medicine" 8th ed. p. 403. This reagent is diluted 1 in 3.

3 **20 per cent sodium carbonate (w/v)**—20 g. of anhydrous sodium carbonate are dissolved in warm water and made to 100 c.c.m. This solution is preserved in a warm place otherwise the sodium carbonate tends to crystallise out.

4 **Stock standard phenol** (100 mg per 100 c.c.m.)—1 g. pure crystalline phenol is dissolved in and made up to 1 litre with 0.1 N HCl.

5 **Diluted stock standard phenol** (10 mg per 100 c.c.m.)—Made by a suitable dilution of (4). (This keeps for at least three months in the ice box.)

6 **Standard-phenol-solution and reagent** (1 mg phenol per 100 c.c.m.)—5 c.c.m. of diluted stock standard (10 mg per 100 c.c.m.) and 15 c.c.m. diluted phenol reagent are made up with water to 60 c.c.m. This solution should be made freshly for use, but will keep several days if preserved in the ice-chest.

IV—Plasma Chloride

The blood plasma of normal persons contains from 560–620 mg. of chlorides (per 100 c.c.m. expressed as NaCl). A decreased plasma chloride may occur in febrile conditions particularly pneumonia, Addison's disease and in cases of gastro intestinal disturbances associated with vomiting or with diarrhoea.

PRINCIPLE

The method is based on the reaction

Silver iodate in ammoniacal solution is added to the deproteinised filtrate of blood or plasma. The excess of silver iodate together with the silver chloride formed is precipitated by the addition of acid leaving in solution an amount of soluble iodate equivalent to the amount of chloride originally present. After the addition of potassium iodide the amount of iodine set free from this soluble iodate is determined by titration with thiosulphate.

METHOD

0.2 c.c.m. of plasma is added to 1 c.c.m. of water, 0.4 c.c.m. of zinc sulphate solution and 0.4 c.c.m. of 0.5 N sodium hydroxide are added and thoroughly mixed. The mixture is then centrifuged 1 c.c.m.

of the supernatant liquid ($\equiv 0.1$ c cm of plasma) is treated with silver iodate reagent (0.5 c cm) and after mixing, with 2 N sulphuric acid (0.5 c cm). The mixture is shaken and filtered through a small fine paper 1 c cm of filtrate ($\equiv 0.05$ c cm of plasma), with the addition of 1 c cm of 1 per cent potassium iodide, is titrated with 0.005 N sodium thiosulphate, with starch as indicator (Haslewood and King 1936).

CALCULATION

Chloride (as mg NaCl/100 c cm of blood) = $97.5 \times \text{titre}$

SOLUTIONS

Preparation of silver iodate reagent—Silver iodate is prepared by mixing equimolecular solutions of silver nitrate and potassium iodate. The precipitate is filtered, washed with distilled water, dried in vacuo, and preserved in the dark. 2 g of the dried solid are dissolved in 100 c cm N ammonia. Both silver iodate and its ammoniacal solution appear to decompose slightly when kept, with liberation of soluble iodate. Immediately before a series of determinations, therefore, 5 c cm of the stock (2 per cent) ammoniacal silver iodate are acidified with 2 N sulphuric acid (5 c cm) and centrifuged. The supernatant fluid is discarded and the iodate redissolved in 5 c cm of fresh N ammonia.

C—PHOTOMETRIC MEASUREMENT WITH THE ORDINARY COLORIMETER

Photometric measurement of the intensity of colour in a solution is preferable, for analytical

Absorption curves of standard solutions (neutral grey screens spectral filters). Yellow solution neutralised ammonium chloride solution (strong uric standard). Red solution density 0.75. Red solution bilirubin standard 0.1 mg in 25 c cm (Haslewood and King 1937). Neutral screen density 0.5. Blue solution uric acid standard neutral screen density 0.5.

purposes, to colorimetric comparison with standard solutions. More accurate measurement of the colour is possible, and interference by extraneous colours—a source of frequent trouble in colorimetry—can be avoided. Photo meters are, however, expensive, and most laboratories are already equipped with colorimeters of the Duboscq type. By the use of light filters and neutral grey screens it is possible to make photometric measurements with the ordinary Duboscq colorimeter. By placing the light filter on the top of the eyepiece, and using daylight or artificial illumination,

The spectral filters of Messrs Ilford Ltd are appropriate for the purpose. A set of 8 mounted glass (grade A) in 1 in. diameter is suitable and can be obtained covering the visible spectrum.

virtually monochromatic light is obtained. Neutral grey screens serve as standards of light absorption. The neutral screen is placed on the left hand rack of the colorimeter, and the rack screwed up till the screen is against the bottom of the plunger. The coloured solution is placed in the right hand cup and its depth is adjusted until the two fields appear equal. This depth gives the measure of the light absorbed by the solution, which is equal to that absorbed by the neutral grey screen. The absorption will vary for lights of different wave length as given by the different filters. With the filter showing maximum absorption the reading (millimeters of solution) will be minimum, and the depths of two different solutions of the same coloured substance should be in inverse ratio to the strengths of the solutions. Generally speaking absorption will be found to be maximum for red solutions in the green or blue green, and conversely, green solutions will show maximum absorption in the red. Blue and violet solutions are maximally absorbing in the yellow, orange, and red, and yellow and orange solutions in the blue and violet.

The grey screen of an appropriate density, together with the light filter showing maximum absorption may be used as a permanent standard for any colorimetric method. It should be calibrated against the coloured solution of known strength—the “standard”, and the general equation for calculating the result for an unknown solution—the “test”—then becomes—

$$\frac{\text{Read of std against grey screen}}{\text{Read of test against grey screen}} \times \text{Conc of std} = \text{Conc of test}$$

When comparison of an unknown solution with a known standard of the same substance is made, using the light filter showing maximum absorption, the accuracy of matching is increased, and interference by other contaminating colours is minimised because they are not maximally absorbing for light of the wave length being used.

WEMBLEY HOSPITAL—The demands upon this institution are very heavy, and ever increasing, and an extension scheme has been prepared which will cost £28,000. A nurses' home and more accommodation for women and children will be provided.

WOMEN IN SOVIET RUSSIA—The central statistical department of the State Planning Commission of the U.S.S.R. announces that in 1936 the number of women employed at the factories in agriculture, transport, trade, public catering, health protection, education, &c. was 8,492,000 forming 34 per cent of the total number of employed workers. There were 15,338 women scientific workers and 42,333 women doctors—a little less than half the total doctors in the country. The number of welfare centres for mothers and infants grew from 247 in 1928 to 3945 in 1936, and during the same period the number of maternity beds increased from 32,773 to 48,250.

SPECIAL UNITS OF THE L.C.C. HOSPITAL SERVICE

A FEATURE of the hospital organisation of the London County Council is the segregation of certain types of cases requiring special treatment so as to allow of this treatment being under the control of teams of consultants skilled in the various specialities. The advantages are obvious: the comparison of results in a large number of cases is clearly of more value when these are under unit control, with accessory factors such as nursing personnel kept constant, multiplication of consultants and of equipment is avoided, and the reservation of a number of beds in one hospital for the same type of case enables the resident staff both medical and nursing to become specially skilful in its treatment.

Brief accounts of the work of these special units during the past year may be read in the Annual Report of the London County Council 1935 (Vol. IV Part III Public Health—Medical Supplement to the Report of the Hospital Services¹).

The *puerperal fever unit* at the North Western Hospital was in the charge of Dr A. Joe, with Dr Hilda Davis as assistant medical officer and Dr J. M. Wyatt as consultant obstetrician. 184 cases were treated during the year of which 166 were of uterine sepsis and associated complications with 11 deaths; the fatal cases are subjected to detailed analysis. Urinary infections complicated 42 out of the 166 cases of uterine sepsis. Towards the latter part of 1935 5 cases of *B. coli* infection were treated with mandelic acid when they had passed the acute febrile stage; in all the urine became sterile after a period of between 7 and 17 days.

A report on the *radium centre for carcinoma of the uterus* at the Lambeth Hospital supplies a very detailed table showing the cases of carcinoma of the cervix or corpus treated during each year from 1928 to 1934, divided into stages and differentiated between those confirmed histologically and those not confirmed. This table and the comments on propaganda on p. 92 merit serious attention. The gynaecological surgeon to this centre is Mr Arnold Walker, with Sir Comyns Berkeley as consulting gynaecological surgeon.

Mr George Stebbing, the surgeon specialist, Dr P. Berry, Dr T. M. Robb, and Mr L. H. Clark as physicist report on the radiotherapeutic clinic at the Lambeth Hospital. During the year under review 567 new patients were placed on the records of this clinic. A number of patients who had already had treatment by surgical operations or by radiotherapy elsewhere and had tumours at a very advanced stage were not included among these 567 cases as they were deemed unlikely to respond favourably though palliative treatment was expected to make them much more comfortable. The results obtained are set out in tables which show the crude survival rate up to five years for those treated in 1930 and since special attention is paid by the clerical staff and a lady almoner to following up patients it seems likely that these will yield very valuable statistical material in a few years. An account of the method of following up is instructive.

One of the most successful is the *plastic surgery unit* at St. James' Hospital under Sir Harold Gillies, Mr T. P. Kilner, and Mr A. H. McIndoe. During the year ended Dec. 31st 1935, 274 patients

were admitted, some of whom had come from as far as Scotland, Wales, and Devon. The classified list of cases treated shows a great number of operations for facial scars and nasal fractures. Cleft lips and palates also figure largely. Skin grafts of every description have been used by far the greater number being Thiersch grafts. Interest has been aroused by the promising results obtained in the surgical treatment of active lupus, and it is most encouraging to find that repair of cleft palate in infancy has resulted in such perfect results that the children seen years later are found to speak normally without speech training.

Sir Leonard Hill reports on the *arthritic unit* at St. Stephen's Hospital. A method of treatment is being tried in the rheumatoid type of arthritis which consists in lavage of the joint combined with synovectomy at an early stage of the disease. This gives an opportunity to Mr Timbrell Fisher and Dr G. H. Eagles to study early histological changes in the synovial membrane and in the joint fluid. Dr Claude Elman is investigating the results of gold therapy in the treatment of chronic infective arthritis.

Two *thoracic surgery units* have been established, one at St. Andrew's Hospital and one at St. James' Hospital. A great number of operations are being carried out on cases of chronic pulmonary tuberculosis. The operations done included thoracoplasty, phrenic evulsion, thoracoplasty and division of adhesions, and apicectomy. Dr J. W. Lunnell, working at St. Andrew's with the late Mr H. P. Nelson, also dealt with cases of intrathoracic new growth, lung abscess, and empyema. The only unsatisfactory results reported were in cases of tuberculous empyema and pyopneumothorax. Despite repeated irrigation and aspiration and intercostal drainage in secondarily infected cases, the efforts to prepare them for thoracoplasty have been disappointing. Of 5 cases of chronic non-tuberculous empyema on the other hand 3 were complete successes and of 8 cases of abscess of the lung, 6 recovered and this is as the authors say a highly satisfactory proportion in such a serious malady. The importance of good team work and in particular of highly skilled nursing is emphasised by the medical superintendent of St. Andrew's, Mr A. Tudor Edwards, working with Mr R. C. Brock and Mr L. O. Shaughnessy, reports on the second year's work at St. James' Hospital. Amongst 153 operations performed there were 27 thoracoplasties and 47 operations for acute empyema and 19 for chronic empyema.

A *goitre clinic* has been in existence at New Lnd Hospital since 1932. Cases are transferred to this clinic from the Council's hospitals and about a third come from outside the L.C.C. area. The patients are encouraged to attend the clinic at intervals after their operations and an effort is made to keep in touch with them by questionnaires. The majority of the 100 patients treated in 1935 were suffering either from primary Graves' disease (40 cases) or from thyrotoxic goitre (46 cases). 104 operations were performed, the majority under a combination of avertin, local infiltration and gas-and-oxygen and there were no deaths. The consulting staff are Sir Thomas Dunhill, Mr Coeffier Keenes, and Dr J. Ingham.

Dr A. F. R. Dewar gives an interesting account of the running of the *diabetic clinic* at St. George in the East Hospital and of the principles observed in the control of glycaemia in patients of different age groups. The avoidance of the danger of hypoglycaemia in the school child by the administration

daily of insulin in several small doses is considered. In the middle aged—i.e., those whose ages range from 45 to 60—the difficulty has not been so much in control of the main diabetic symptoms as in prevention of degenerative lesions, particularly of the nervous and cardiovascular types. Fibrositis is also an urgent problem. A high blood sugar is not regarded as the prime factor responsible for these degenerative changes. Dr B. A. Young, in reporting on the diabetic clinic at St Peter's Hospital, discusses the relative importance of urine analysis and of blood analysis in controlling the treatment. He says that at his clinic it is the practice to endeavour to keep the blood sugar within normal limits in younger patients. In the older patients urine analysis is often sufficient. In diagnosis, blood sugar estimations are, of course, necessary. Self administration of insulin is taught wherever possible. If the patient cannot be taught, a responsible relative is often available. St Peter's Hospital have been fortunate in having the co-operation of the East London Nursing Society who have administered insulin and helped in the education of the poorer diabetics. The higher carbohydrate diet combined with the low fat diet advised by Watson and Wharton has been successful in trials at St George in the East.

A congenital syphilis unit, with residential treatment for the children, at St John's Hospital is under the supervision of Dr David Nabarro. Twelve new cases have been admitted during the year, 9 boys and 3 girls, and there were 11 readmissions, all girls. Dr Nabarro reports that the progress made by the children is good and fully justifies the provision of residential accommodation. His only regret is that so few of the admissions are of infants under the age of 2-3 months, for it is when started at this early age that treatment is most likely to result in cure. Even better results are obtained by treatment of expectant mothers.

The urological unit at St Mary Abbots Hospital comprises two wards, male (28 beds) and female (25 beds). Under the auspices of the Medical Research Council the effect of Hombroek on prostatism is being studied. The number of cases has been small owing to the fact that before any research can be carried out the patients must be free from urinary infection. It is stated that the results as far as can be ascertained have not been satisfactory. A follow up department has been established for prostatectomies and stricture cases, patients from other hospitals may attend this clinic for dilatations. A total of 165 operations were performed during 1935, and the report of the medical superintendent, Mr James Carver, shows that a great variety of genito-urinary diseases are dealt with. Curiously enough, amongst 248 admissions there were only 2 cases of tuberculosis of the kidney and none of tuberculosis of the testis. Urinary infection accounts for 83 admissions, stricture of the urethra for 18, and enlargement of the prostate for 26. The other cases cover a wide field.

Mr D. A. Benthie reports on the fracture clinic at Fulham Hospital. He emphasises the importance of segregation of these cases on admission to hospital. The two wards available at Fulham are equipped with special power points for the use of portable X ray plant and with fracture beds of the Maurice Smoliar type, that can be tilted by means of pulleys fixed to the ceiling. By collecting the cases in one ward the training of the nursing staff is made much easier and more efficient. In treatment of out patients ambulatory plaster methods are employed,

and every fracture case that has been treated in hospital attends. The senior member of the massage department is always present to ensure the closest possible co-operation between the surgeons and the masseuses. The records are kept in a filing system that renders them easily accessible at any time. The patient's notes are filed with the X rays in one envelope inscribed with his name and number. A viewing box forms part of the equipment. The average number of patients attending the weekly sessions of the clinic vary between 38 and 45. In addition to fracture cases, all orthopaedic patients of the out patient type and any out patients referred for massage treatment are kept under observation at the clinic.

UNITED STATES OF AMERICA

(FROM AN OCCASIONAL CORRESPONDENT)

THE American Foundation Studies in Government published on April 5th its report on medical care in the United States¹. This report is significant both as a contribution to the science of government and as a presentation of the serious thought of the profession most concerned upon the urgent social problem of providing "adequate" medical care to the people. The work of organisation, of review, and of compilation involved in this study must have been tremendous. Wealth alone could not have accomplished it. The Foundation has been well served by research workers with both imagination and ability.

The report is based on some 5000 letters from more than 2000 carefully selected physicians located in all parts of this country. It represents the views of individuals rather than of organisations. At the same time anonymity has been preserved in order that the facts and arguments presented may stand on their own authority. The reader is obliged to rely upon the Foundation for the verification of statements, but he will probably be willing to do so both on account of their general reputation and the evident competence displayed in the preparation of this report. English readers may find it difficult to appreciate how greatly American readers might be affected by the publication of names in this very controversial discussion.

This study does not "prove" anything. It was not intended to do so. What it must do is to promote thought, broaden understanding, and dissolve prejudice. Incidentally it will be a "source" book for sociologists and serious students of government in universities all over the world. For the problems with which it deals are by no means peculiar to the United States.

DISCOVERER OF ETHER ANÆSTHESIA

A MEMORIAL to Crawford Williamson Long, American discoverer of ether anæsthesia, was unveiled in the library of the Royal College of Surgeons in Edinburgh, last week. The memorial is a plaque which has been presented by the Southern Society of Clinical Surgeons, U.S.A., in appreciation of their reception in Edinburgh during their visit in 1936. Dr Long (1815-78) made his discovery at Jefferson,

¹ American Medicine. Expert Testimony Out of Court. The American Foundation Studies in Government. 365 Fifth Avenue, New York City. 1937. Pp 1500 (2 vols.) £3 50 for both volumes.

Georgia on March 30th 1842 Mr L B Wevill F.R.C.S.E. who was introduced by the president of the College, pointed out that this remarkable discovery was made by an unknown young general practitioner working in a small country town. The effect of inhaling nitrous oxide or ether was at the time used by itinerant chemists to cause amusement. Long observed that during these frolics the subjects of the experiment did not complain of pain when they injured themselves. He therefore proposed to a certain Mr Venable one of his patients who required to have a wen removed that here might be a way to have the operation done painlessly. On March 30th 1842 this experiment was carried out with complete success.

POST GRADUATE TEACHING

The syllabus for post-graduate teaching in Edinburgh has just been published. Apart from the usual summer courses arrangements are being made for an intensive eight weeks medical course to be held next autumn. There will be four hours of coordinated teaching each day during the course and special facilities for the study of clinical methods and ward work.

IRELAND

(FROM OUR OWN CORRESPONDENT)

MEDICAL ATTENDANCE ON THE CIVIC GUARD

A few weeks ago Mr Rutledge Minister for Justice received a deputation from the Council of the Irish

Free State Medical Union to hear their views on the method ordinarily employed for the appointment and remuneration of medical attendants to the Garda Síochána in country districts. It was pointed out to the Minister that when a vacancy occurred in the position of medical attendant to the Garda it had become the custom for an officer of the Force to invite the medical practitioners in the neighbourhood to tender for the post, stating the fees they would be willing to accept for the several services rendered. The practitioner who was willing to accept the smallest fees was usually appointed. The Minister without admitting that the deciding point was the size of the fees demanded recognised that the present method was unsatisfactory and promised to endeavour to alter it. The matter was raised again in the Dáil last week in the debate on the estimates by Dr R. J. Rowlette who had called attention to it previously two years ago. He also commented on the fact that the State did not supply a full medical attendance to members of the Garda but only what might be called a general practitioner service. If a guard had to seek the advice of a specialist or to enter hospital he must do so at his own expense. He suggested that a guard should not be in a worse position than a soldier as regards the care of his health by the State. There should be an efficient medical service provided by the State for its servants. The Minister in reply stated that the question of remuneration was the subject of communication between his Department and the Department of Finance and he hoped for a satisfactory result.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg Comdr R. L. G. Proctor to *President* for course
Surg Comdr J. S. Elliot and L. S. Goss, O.B.E. retire at own request with rank of Surg Capt
Surg Lt-Comdr T. W. Fleggatt to *St Angelo* for R.N. Hosp Malta. J. J. Keovil to *Leander* and lent to N.Z. Division for three years and E. J. Mookler to *Ganges*
Surg Lts W. W. Skimins to *Furious* and T. McCarty to *Drake* for R.N.B. and to *Centurion* (on coming)
Surg Lts for Short Service G. L. Hardman (St George's Hosp.) J. F. Moyneil and W. S. Parker (Mauclerk Univ.) and W. B. Teasey (Queen's Univ. Belfast)
Surg Lts (D) H. Bradley Watson to *Penbrooke* for R.N. Infirmary Deal and S. R. Wallis to *Royal Sovereign*
W. G. Smith and E. B. Mackenzie to be Surg Lts. (D)

ROYAL NAVAL VOLUNTEER RESERVE

Surg Lts F. T. Land promoted to Surg Lt-Comdr and G. C. Martin transferred from List 1 of the Reserve Division to List 2 of the London Division
Prob Surg Lt J. K. Sargentson to *Ramillies*

ARMY MEDICAL SERVICES

The War Office announces that Col G. G. Tabuteau D.S.O. late R.A.M.C. has been promoted to the rank of Major General with effect from April 1st and will continue in his present appointment as Deputy Director of Medical Services Northern Command.

Major-General Tabuteau received his medical education at the Royal College of Physicians and Surgeons Dublin and entered the R.A.M.C. in 1905. He was promoted Lt-Col in 1920, Major-General in 1932 and Col in 1934. He served in France and Belgium during the Great War and in addition to receiving the D.S.O. was twice mentioned in dispatches. He also served in Waziristan (1912-21) and in Burma (1920-32) being mentioned in dispatches for the latter service and receiving the brevet rank of Col.

Maj Gen FitzG G FitzGerald C.B. D.S.O. K.H.S. late R.A.M.C. is placed on half pay under the provisions of Art. 500 Royal Warrant for 1st and Promotion 1931
Col A. Dawson O.B.L. late R.A.M.C. retires on first pay

Lt Col H. Gall from R.A.M.C. to be Col
Lt-Col A. N. McNeill D.S.O. from R.A.M.C. to be Col

ROYAL ARMY MEDICAL CORPS

Majs to be Lt Cols: R. H. Alexander M.C. R. W. Galloway D.S.O. W. Frier and F. G. Flood M.C.

REGULAR ARMY RESERVE OF OFFICERS

Maj G. M. Rigby having attained the age limit of liability to recall ceases to belong to the Res. of Off.

SUPPLEMENTARY RESERVE OF OFFICERS

Lt R. L. Walmsley to be Capt

ARMY DENTAL CORPS

Maj J. H. W. Fitzgerald having attained the age for retirement is placed on ret pay
Short Service Commissioners—Lts to be Cpts R. Walker D. V. Taylor and D. S. Wilson

ROYAL AIR FORCE

Wing Comdr B. F. Haslethorpe to R.A.F. Station Ceshot for duty as Medical Officer
Squadron Leader C. G. J. Nicolls to R.A.F. Station Gosport for duty as Medical Officer
Flight Lt O. S. M. Williams to Princess Mary's R.A.F. Hosp. Halton
Flying Offr R. F. Courtin to R.A.F. Depot Uxbridge

DEATHS IN THE SERVICES

The death occurred on March 14th at South of Lt Colonel ROBERT GALE D.S.O. R.A.M.C. retired. Born in August 1887 he was a son of the late Mr Laurell Gale and was educated at Glasgow University and graduated M.B. Ch.B. Glasg. in 1909. He entered the R.A.M.C. in the same year, became captain in 1913 and major in 1921. From 1911 to 1914 he was in civil employment in Egypt, and then served during the European war to 1918, being mentioned three in dispatches and created D.S.O. in 1915. In 1934 he was Deputy Assistant Director of Medical Services Northern Command at York. In 1916 he married Lora, daughter of the late Mr R. F. Alexander of Glasgow, and leaves a son and daughter.

GRAINS AND SCRUPLES

Under this heading appear week by week the unfettered thoughts of doctors in various occupations. Each contributor is responsible for the section for a month, his name can be seen later in the half-yearly index

FROM A TADDYGADDY

II

"Of his works there is no end" The man who wrote that was thinking of us as we were more than two thousand years ago the ordinary plodding day in day out G.P.'s of his time. We don't seem to have changed much. We still are slaves of the night bell and the inconsiderate friends of the patient who never think of sending till after hours. He was an observant chronicler. Did he not go on? "From him is peace over all the earth."

Our remote predecessors knew enough to carry with them always a few opium pills, or their equivalent, so that, once disturbed, they would not get a second message on the same night from the same restless patient. Yet was he thinking merely of the comfort, or discomfort, of the doctor? Assuredly not. That writer, Jeshua Ben Sira, thought many wise thoughts and, fortunately, wrote them down. When he wrote about us and peace he was thinking—can we doubt it?—of the part other wise men might take in ensuring it. Is it arrogant if we, the doctors of to-day, claim to be numbered with the wise? We may not have any very great store of book learning—in our student days we were compelled to the study of books that were hardly books at all in the proper sense, but if we are not wise it surely is our own fault. We are thrown, whether we like it or not, into the intimate company of men and women of all sorts. If we do not learn wisdom from them we shall learn it nowhere.

* * *

"From him is peace" Why not? The statesmen talk of war and preparations for war. That way come death and destruction. We are doctors. Our job is the prevention of death, when possible, the alleviation of suffering. Actually we are, or should be, at variance with the statesmen in so far as they consider war inevitable. But are we? And now, somebody will say, I am becoming political. Maybe. But I am content to walk with Ben Sira. He also was political, but he knew how to write. And he was always on the side of righteousness. Somehow I cannot help feeling that if we doctors would we could do a vast deal in the direction of fostering world peace. In our time we have seen so much of the personal effects of war. Potentates pay ceremonial visits to hospitals where they are shown the more presentable cases and say the appropriate things. We see the men who, owing to the activities of flying bits of jagged hot metal, or of noxious gases, are no longer capable of controlling their more unpleasant functions. We know, from personal observation, that war means something even more horrifying than a patch of country littered with corpses. It means here and there an assembly of men, still alive, but no longer men as men were meant to be. Do the statesmen—it matters little whether they are, or are not, dictators—ever think of those half men?

* * *

What about that old time sentence, "From him is peace over all the earth?" Has it any meaning for us? We do not let us forget this, our members

of a corporation that is international as no other corporation except the Catholic church is international. To a doctor any other doctor is as he is—just a doctor. We have no secrets we will not share. If you or I, English doctors, happen to stumble on something that will help matters in the struggle with—shall we say, the common domestic cold in the head?—we pass it along as quickly as the postal authorities will permit to the uttermost parts of the earth. We are no more respecters of narrow nationalism than were the wandering scholars of the days of faith. They tramped from university to university, from monastery to monastery, from bishop's palace to bishop's palace, swapping manuscripts, gossip, and ideas. So is it with us, with this exception—we do not have to tramp. And yet, in spite of all our heaven given opportunities, we are content to let our power run to waste.

* * *

It was another Hebrew who wrote "Wisdom went forth to make her dwelling place among the children of men, and found no dwelling place. Wisdom returned to her place, and took her seat among the angels." It is not surprising that he wrote thus. Between his time and the time of Ben Sira his country had been a battlefield for a couple of hundred years. Ben Sira had looked forward. That later writer looked back. And we—in what direction do we look—we, the doctors of this much later age?

* * *

My working life has been spent in and about back streets, and long before it began I wandered in and out of the homes of the poor with my father, who was essentially a poor man's parson. As a child I numbered many old women among my friends. There was one who lived in a single room with a parrot and, during the proper season, a great cardboard box in which silkworms grew fat on a diet of lettuce leaves until they shut themselves up in cunningly spun prisons of gleaming silk. She and I shared a secret hope—that some day we should gather a pound of yellow silk thread, for then we should be paid a whole sovereign. We never did. Once I found that old woman in a state of dire distress. She had upset her cardboard box, and the silkworms were loose in her bed. However, I collected them for her and all was well. There was another old woman who had as sole companion a bantam hen. She used to give me bantam's eggs which were served up for my breakfast in a wooden egg cup decorated with a picture of the Crystal Palace given me by another old woman. And this very evening an old woman, very poor, she lives in a single room in an alms house—has come to see me because she has a sore throat. That is unusual. As a rule when she comes it is to press upon me a bottle of home made wine of her own brewing. And the point of all that personal chronicle is just this, that all these old women were friendly. They asked no more than that they might be at peace with everybody else. And is it not so generally? In back streets people quarrel one with another. There are family feuds. But let trouble happen along—the feuds are forgotten, are put on one side. Mrs. Jones will sit up all night with her enemy Mrs. Smith, and

then go off to her work next morning without turning a hair. Forty years in and about back streets have shown me something of the inherent friendliness of people.

* * *

Is it surprising that I an ordinary average G.P. a Taddygaddy fall entirely to understand why it is the statesmen seem to think war inevitable? I have gone about my business for many years in quarters that were terribly overcrowded but very seldom have I heard any suggestion from the people living there that they shall go and seize by force more roomy quarters. The governing people of Europe would be horrified if the common people did that. Yet they have no hesitation in doing it themselves. They call it expansion. In furtherance of their policy they employ any sort of devilish device that comes to hand. They burn and blister and blow up any who have the temerity to get in their way and leave us to do what we can in the way of repair. We can do something for the burned and the blistered but those effectively blown up are beyond our power to help.

* * *

World politics to every experienced Taddygaddy must seem entirely mad. The one remedy that may even yet, be effectual is ridicule. The statesmen of Europe seem to have forgotten how to laugh. But

we have not forgotten. A Taddygaddy an ordinary G.P. who has forgotten how to laugh is no longer a Taddygaddy. He has become no more than a medical man—a tradesman hawking his wares in hope of profit just that, and no more than that. We have not arrived there yet. We still are a profession that takes no heed of national boundaries. To us it matters not at all whether another doctor be French or German or Jap or English. We do not ask a sick man to produce his passport before we offer our services. All we ask of the foreign doctor is that he shall help: of the foreign patient that he shall accept.

* * *

We have our ideals. They are very largely the ideals of the mediæval church which took small stock of narrow nationalism preaching—even when it did not practise—international brotherhood. The church had this at least, a common language. The clerk, wherever he went could talk to fellow clerk. That made for international unity so far as the clerks were concerned. We the doctors of the world may go further if we will. We have no common language unfortunately. We no longer express ourselves in Latin as did that great pathologist Shattock not so long ago. But we have this in common with all doctors—sympathy of aim. Cannot we urge that upon the politicians? They might they might see what it is we are getting at.

PANEL AND CONTRACT PRACTICE

Black coated Workers

THE text of the Widows Orphans and Old Age Contributory Pensions (Voluntary Contributors) Bill, 1937 was issued on March 23rd. Health and pensions insurance have been so interlocked hitherto that it is not surprising that some practitioners have wondered whether the Bill may bring into medical benefit persons who have previously been excluded. This is not so. The purpose of the Bill is simply to extend the benefits of voluntary insurance for widows orphans and old age pensions to persons with small incomes whether working on their own account or not who have not the qualification of insurable employment required under the present scheme. The persons now rendered eligible for pensions will include ministers of religion shop keepers farmers dressmakers and music teachers. Its provisions will give them no claim for medical sickness, or disablement benefit. The scheme not being compulsory the full pension will be dependent upon the payment of a certain number of contributions. If the average falls below that number the rates of pension (normally those provided under the Contributory Pensions Act of 1936) will be reduced. Applicants for admission to insurance must have been resident in Great Britain for at least ten years, their income at the time of application must not exceed £400 a year for men £250 for women and in either case up to half may be unearned. For the first year applicants not exceeding 55 years of age at the commencement of the scheme will be admitted at 1s 3d per week if insured for all benefits or 10d a week for widows and orphans pensions only. Women initial entrants will be insured for old age and orphans pensions for 6d. a week. After the first year applicants must not be more than 40 years of age at the date of application and their contributions will vary in accordance with their age at entry. The main qualifying conditions for a pension are as follows:

For a widows or orphans pension.—104 weeks of insurance and payment of 104 contributions since the date of entry into insurance.

For an old age pension.—Continuous insurance for at least ten years immediately prior to attainment of the age of 65 and payment of 260 weekly contributions.

Full pensions will be paid only if there is an average of at least 50 weekly contributions per annum throughout insurance.

Mixed Partnerships

Dr A resigned from an insurance committee's list in the hope of securing an appointment as head of a department for psychological treatment to which his having an insurance practice would have been a bar. He transferred his insured patients to another member of his firm two of whom were under agreement with the committee. Dr A wished to attend insured persons on behalf of his partners but the committee were of opinion that it is undesirable for the partner of an insurance practitioner not to be under contract to treat insured persons, inasmuch as misunderstandings and abuses might arise from the treatment of insured persons by a non insurance practitioner. The committee made a further point his partners might call Dr A in as consultant when he was not the best specialist for the purpose because his fees would form part of the firm's income. The matter was referred to the Ministry of Health which replied thus:

The Minister of Health is advised that there is no legal objection to the partner of an insurance practitioner not being under contract with the insurance committee, and the Minister has no information which would lead to the conclusion that such a partnership is an undesirable one tending to lead to misunderstanding and abuse. The Minister sees no ground on which exception could be taken to the giving of treatment outside scope by the non insurance partner. If an insurance practitioner refers one of his patients to his non insurance partner for treatment outside the scope of an insurance practitioner's obligations no case could lie against

him unless it were shown that he had not faithfully discharged his duties if the non insurance partner had the necessary qualifications for undertaking the treatment, the fact that some other practitioner might be better qualified would not necessarily indicate non compliance with the requirements of Clause 9 (1) "

The Insurance Acts Committee has recently had under consideration a communication from a provincial panel committee raising the question of partnership between a practitioner who is doing insurance work and one who is not. The question had arisen because of a suggestion from the insurance committee concerned that the partner with the private practice only should agree not to charge

fees to his partner's insured patients. In 1934 the annual panel conference referred to the I A C a motion by Lancashire in the following terms

"That in the opinion of this conference an arrangement whereby an insurance practitioner has any partnership with a doctor who is not on the medical list is prejudicial to the observance of the regulations governing insurance practice and must of necessity conduce to abuses in the matter of receipt of fees by insurance practitioners from patients on their lists "

The I A C's view was that any abuses which could be attributed to such a partnership occurred so seldom as not to demand a special regulation, and the 1935 conference concurred in this view

PUBLIC HEALTH

1936 in Scotland

DETERIORATION rather than improvement in the health of Scotland during 1936 is shown by the report of the Department of Health just issued. The infantile mortality rate rose from 77 in 1935 to 82, which compares very unfavourably with England's rates (57 and 59 respectively). Maternal mortality fell from 63 to 56 per 1000 live births, but even the latter rate is higher than it ought to be. The slight rise in the general death rate, from 13.2 to 13.4, and the slighter increase in tuberculosis mortality can be put down to epidemic prevalence of influenza. The history of infectious disease in Scotland in 1936 was not sensational, though the biennial epidemic of measles was sharper than usual, there was an unusual amount of poliomyelitis in autumn in south east Scotland, and several small outbreaks of paratyphoid occurred, especially in the west. As in the rest of Britain and most parts of Europe, diarrhoeal diseases (including the typhoid and dysentery groups) were more prevalent in 1936 than for many years.

The Scottish Office provides an annual report on the health of insured persons, which is the most reliable of the meagre reports on morbidity available. We read that it is "disappointing that the completion of a quarter of a century of National Health Insurance leaves the incidence of incapacitating sickness so high—at eleven days per insured person per annum and the figure is not declining." But in two places attention is called to the higher standard of health demanded which causes employees to go off work earlier and more frequently and to return to work later than they did in the past. To what extent this leads to better health is one of the chief medico-social problems before us at present. Attention is called to the increase in chronic incapacity not attributable to the increased age of the population and an alleged increase in deaths from rheumatic heart disease amongst the young. "Year after year at least 1000 lives are lost from this type of heart mischief in Scotland." Housing in Scotland is notoriously bad, but it is astonishing to read that overcrowding is six times as common as it is in England. The paragraph on housing gives the impression that the Department attributes much of the avoidable ill health of Scotland to bad housing.

A chapter on food supply opens by describing a milk feeding experiment on school children in England and Scotland. A third of the children were given daily a third of a pint of pasteurised milk, another third were given two thirds of a pint of pasteurised milk and the remaining third were given two thirds of a pint of raw milk. No difference was detected between the pasteurised and raw milk groups, but

the two thirds pint children did better than the one third pint. The milk in schools scheme, similar in Scotland to what it is in England, is having the same history. After the first spurt there was a big reduction in the numbers of school children paying for the milk, though recently the tide has turned and there is a slight increase. The reasons assigned for what must be considered a partial failure of the scheme can be divided into excuses that should be ignored and grievances that should be remedied. The latter are three in number: novelty worn off, mid morning milk spoils the appetite for dinner, parents resent paying for what some can obtain free. The first is the most important. The milk in schools scheme was introduced to foster the habit of milk drinking, but so far its success in that direction has been poor, for the habits of the people are not to be changed in a few months. It is necessary to make the milk in school a more intimate part of education if it is to engender a permanent habit of milk drinking. If eleven o'clock milk were called an aperitif instead of a milk ration it might increase and not diminish appetite for the midday meal! In any case the drink can be retimed. From Dundee comes the admirable suggestion to give the ration between 9 and 10 o'clock because "it would be of benefit to such children as had had only a scanty breakfast." There is general agreement that a third of a pint of milk is insufficient, and a growing tendency to give more of it free.

An Epidemic and the Public

In the late summer of last year there was an outbreak of typhoid fever in the Bournemouth district in the course of which 523 cases were notified to the sanitary authorities of Bournemouth, Poole and Christchurch, and 41 deaths occurred. Complaint was made in the local press against the local authorities that they had not taken the public into their confidence at a sufficiently early stage. There was in fact a suggestion that an endeavour had been made to conceal from the public the true facts about the outbreak. At the request of all the parties concerned, Judge Cotes Preedy held a private inquiry, the report of which was issued on Tuesday. In his view, once the situation was established, there was no endeavour on the part of the authorities to conceal the true facts about it, he thought the official would have acted unwisely if they had sponsored the announcement in the press of an existing epidemic directly suspected cases had appeared. It was common knowledge, he remarks, that sporadic cases of typhoid frequently occur and the difficulty of diagnosis called for caution, if only for the reason that a hasty announcement might determine the flight of people carrying the disease to all parts of the country.

CORRESPONDENCE

OVER TREATMENT OF GONORRHOEA

To the Editor of THE LANCET

SIR,—I beg to endorse the views given by Mr Nicholls in your issue of March 20th writing as one who has lived in that dark and uncritical world to which he refers having held posts in venereal disease clinics for over twenty years.

I gave evidence before a subcommittee of a V D hospital more than two years ago and directed attention to some of the points raised by him but do not know with what result. If the total number of attendances rather than the total number of patients is to be regarded as a criterion of good work and monetary grants are apportioned accordingly this system appears to call for the most searching investigation.

Among various types of cases which occur to my mind are those that are treated regularly over long periods by prostatic massage and posterior irrigations usually carried out by orderlies. In a large proportion of these cases the patient complains only of a slight morning urethral moisture and notices threads in the urine. Cultures and films continually taken show only diphtheroid bacilli and staphylococci the prostate exhibits no gross abnormality and the urethra appears normal on urethroscopy. Why are these cases condemned to protracted treatment with the risk of disastrous psychological reactions? Again irritation of the prostate by posterior irrigations and massage during the early weeks of gonorrhoea is in my opinion mainly responsible for the cases of acute prostatitis and epididymitis that are so frequently recorded. A prostate treated with respect and consideration will as a rule, give no serious trouble in the course of the disease. All experience goes to show that the efficiency of any V D clinic depends in great measure upon systematic liaison with various departments of a hospital of which the genito-urinary one is manifestly interdependent.

As Mr Nicholls points out, it is difficult to understand why gonorrhoea should be wedded to syphilis and why an expert knowledge of either disease provides any guarantee whatever of a like standard of efficiency in dealing with the other. It seems obvious that the syphilis department of a V D clinic should be divorced from the gonorrhoeal one; the director of the former having special experience in dermatology, cardiology and neurology and that of the latter in genito-urinary surgery and gynaecology.

Procedure in regard to the segregation of V D cases from others is another matter which demands urgent attention. For example the psychological effects on a man suffering from a non-gonococcal urethritis and prostatitis (now recognised as a common condition) when condemned to make use of the same cubicle and apparatus as a V D patient can be left to the imagination. The female V D department is in my opinion in still greater need of reorganisation. My experience has convinced me that this part of the clinic tends to become a sitting department for a variety of conditions—such as laceration of the cervix following childbirth, prolapse and mycotic diseases of the vulva and vagina—owing to the fact that under the present system a patient complaining either of vaginal discharge and irritation or of painful and frequent micturition is customarily referred to a V D department. This procedure

I submit not only involves a total disregard of the patients' feelings but also makes them reluctant to seek advice.

Some twenty years have elapsed since an inquiry relating to venereal disease was last held in this country. In view of the fact that the London County Council are to expend no less than £55,000 on V D clinics in London during the coming year it seems reasonable to suggest that the time has now arrived for the holding of another inquiry for the purpose of assuring the public that the organisation of these clinics is such that the money provided is being expended in the best interests of public health.

I am Sir yours faithfully

WHO INVENTED THE IDEA OF TARRING ROADS?

To the Editor of THE LANCET

SIR,—In reply to the query raised by A Rusticating Pathologist in Grains and Scruples of March 20th the tarring of roads would seem to have been invented by Sin and Death when they thus treated their causeway across Chaos from Hell to the newly created World (Paradise Lost Bk. 2). The work of consolidating the materials with asphaltic slime appears mainly to have been done by Death, which suggests that the alleged increase of cancer of the lungs in recent times may perhaps be due not to the dusty roads of thirty years ago but to the widespread use since then of so notorious a carcinogenic substance as tar.

I am Sir yours faithfully

New College Oxford, April 2nd

R S CREED

To the Editor of THE LANCET

SIR,—In your issue of March 20th A Rusticating Pathologist begins his article with the statement: No one that I have asked has been able to tell me who invented the idea of tarring roads. It was a great discovery worth a peerage and a fortune as well as the preservation of a name. It may interest you to learn that it was Dr Guglielminetti, a Swiss by origin born in Monthey (Valais) who in 1900 in Montecarlo made the first experiments with tarring roads. As a doctor he was greatly impressed by the dust nuisance and this led him to his discovery. In the French automobile press Dr Guglielminetti has been appraised as le père goudron.

I am Sir yours faithfully

A L VISCHER.

Basel, March 21st

ATHLETICS FOR WOMEN

To the Editor of THE LANCET

SIR,—Your reviewer (March 27th p. 760) of the British Encyclopædia of Medical Practice dislikes my (apparently) old fashioned prejudices against violent exercise for women. Any such objections proceed from a variety of reasons, some perhaps merely a matter of taste, some affording legitimate scope for difference of opinion. It may be true as your reviewer submits that a large number of women condemned to childlessness seek an outlet for their energies in athletics although one may speculate whether some preferable form of sublimation might not be selected. But when he adds that my (presumed) contention that the habit of taking strenuous exercise makes for difficult labour is quite unsupported by evidence he implies that he has

the unanimous support of obstetricians and gynaecologists. A considerable number of eminent obstetricians have assured me that they are fully convinced of the disadvantageous influence of violent and strenuous exercise from their point of view. From my point of view there are other direct and indirect consequences of the strain of intense competition against which I particularly inveigh.

I am, Sir, yours faithfully,

Brook street, W, March 30th ADOLPHE ABRAHAMS

COLOUR PERCEPTION TESTS

To the Editor of THE LANCET

SIR,—In a moderately illuminated spectrum the number of colours seen by different people varies from six to two. The brightest portion of the spectrum is between wave lengths 57 and 61A, and from there the brightness appears to shade into the dark red and violet constituting as it were two areas of brightness, a central very bright area within a larger bright area. The colours in the former are pale greenish yellow, yellow and orange red, whereas the green and red in the larger area are saturated and distinct.

Trichromics and dichromics confuse red, green, yellow, and white signal lights. The only property common to these colours is brightness and the difference in brightness apparently enables colour blind persons to differentiate colours from each other. If this is correct, then mistakes should start in the brightest portion of the spectrum in the earlier varieties of colour blindness and be more and more pronounced till total colour blindness is reached—and this is exactly what occurs. The trichromic, the first stage of dangerous colour blindness, when asked to map out the fullest extent of red will stop short of orange and declare he can see yellow (or white), and when asked to do likewise with this colour will map out an area extending from orange red into a yellow green and declare it to be monochromatic yellow or white, whereas it contains pale red, orange, yellow, and pale green colours. This area corresponds to the brightest portion of the spectrum. He does, however, recognise the more pronounced red and green colours of the spectrum on either side of his monochromatic area. With a lantern examination the same person, if shown similar pale red, green, and yellow colours, will be unable to distinguish them because colours of this saturation and brightness come within his confusion area, but he will not confuse saturated reds and greens which are outside it. This confusion of colour corresponds to the extent of altered colour perception, increasing to a point where it reaches the stage of dichromatism.

Dichromics, when asked to map out the fullest extent of red, will map out an area extending right into blue and consider it red or yellow, and this area will be found to correspond to the larger area of brightness. As this area contains definite red and green colours with a lantern examination, they will mix up saturated red, green, and yellow colours. To the dichromic there is no difference between red and yellow, he is apt to call a yellow green red. The totally colour blind see only a bright area of varying shades of intensity. Looking at the full spectrum, dichromics see a white space of varying size between the red and violet.

There is apparently a definite balance between saturation and brightness on which the recognition of colour depends, and if this balance is upset then brightness gets the upper hand, bright red appears as yellow and violet as blue, giving rise to the

so called 'yellow and blue sensation'. There is not really an increased sense towards yellow and blue, these colours merely appear brighter. In all colour perception tests these facts should be borne in mind. When carrying out book tests care must be taken to make the examination in a bright light to bring out the confusion effect, otherwise varying results will be obtained with the same person by different examiners.

THE ÆTIOLOGY OF PELLAGRA

To the Editor of THE LANCET

SIR,—May I call your attention to an error and a misconception in the report in your issue of April 3rd (p. 811) of my contribution to the discussion on nutrition and its effect on infectious diseases which took place on March 24th at the Royal Society of Medicine. The experiments with pigs referred to were carried out in collaboration with Dr T A Birch, not Bird, and Sir Charles Martin in the department of animal pathology at Cambridge. They were devised to study the nutritive defects of maize in the hope of throwing light on the ætiology of pellagra. On a diet of maize supplemented with pure casein the pigs soon ceased to grow and suffered from diarrhoea. This was apparently due to the combined effect of an intestinal infection and the defective diet, but it was not my intention to convey that the "intestinal condition" resembled that found in human pellagra.

I am, Sir, yours faithfully,

HARRIETTE CHICK.

Lister Institute, London S W April 5th

IMMUNISATION OF MEN—AND ANIMALS

To the Editor of THE LANCET

SIR,—I read with considerable interest your annotation in last week's number on vaccination against African horse sickness, and as a Houyhnhnm I was touched by the solicitude shown by your race for the less fortunate members of mine. This concern for the welfare of beings other than themselves has always seemed to me to be one of the traits which argues that the human race will some day emerge from its present state to something like what we Houyhnhnms would call civilisation. My brother, who has always taken a more cynical view than I of human endeavour, made the remark that had the horses been black instead of being of good British blood, African sickness could have done its worst without attracting much attention. But I pointed out to him that at any rate in large scale commercial undertakings painstaking and praiseworthy efforts are made by the management to prevent tuberculosis and pneumonia from incapacitating or exterminating the native labour force. I had, indeed, been reading your annotator's comments with unqualified gratification until I came to the final paragraphs where after detailing the various dangers and mishaps to horses, which might attend vaccination with neurotropic vaccine, he casually remarked that "these considerations are of minor importance."

So much depends upon the point of view! I confess that both my mane and my tail bristled at your annotator's remark. I could have to some extent understood it had he been referring to the immunisation of human children. I find modern human literature too depressing to read extensively, but from what

little I read and from what I hear from correspondents of my own people in different parts of the world I gather that humankind has definitely made up its mind that it is the State not the individual that matters. Of this I have nothing to say. I am liberal enough to believe that the human species and even such backward members of it as Russians, Germans and Italians know their own business best. But I should like to make it clear that the principle has never been admitted in Houghlinham philosophy and to this we are inclined to ascribe the culture peace and happiness of our society. So far as horses are concerned it must be allowed that their very origin was in the freedom of the unlimited steppes where the family rather than any larger social canvas was the fundamental unit. To an equine it would never appear a sufficient justification of mass immunisation that some other equine's offspring was saved if it were at the expense of unfortunate results of immunisation affecting his own offspring.

It may not be known to your readers that although immunisation methods have been introduced to a limited extent among the Houghlinhams they are only adopted after certain formal preliminaries. If a case has been made out in the laboratory for the procedure, our doctors are permitted to make trial upon themselves. If this is satisfactory (and there are any doctors left) volunteers who are told exactly how things stand are asked for and inoculated. The results on these are handed over to one of the most responsible officers of our State—the Lord Chief Statistician. With us this dignitary's opinions are as valued, his judgments are as binding and his jokes as highly appreciated as with your own Lord

Chief Justice. If his opinion is unfavourable the perpetrators of the false immunisation are severely punished and this perhaps explains why immunisation has never been so popular with us as with you. If on the other hand his opinion is favourable he affixes his seal and the countersign *fiat* (an abbreviation for *fiat experimentum* not for *fiat lex* as might be expected from human precedent). The *fiat* with the relevant data but without further remarks is then promulgated throughout our Commonwealth and any parents who choose may bring their foals to be injected. There is of course no compulsion and that essentially human activity—propaganda—is entirely unknown among us. It is one of the advantages of being a Houghlinham that the steppes are wide and grass is cheap and if we don't like society or its ways we can always lump it.

Mark you I am not denying the general principles expressed in your annotation. I wish merely to point out that though they may be applicable to many species of beings including yourselves they are repugnant to what I would with due modesty call horse sense. The classical human historian of my people (may his great soul rest in peace!) wrote also you will remember a constructive little pamphlet called *A Modest Proposal* for eating Irish children which it has always seemed to me deals admirably with the human aspect of the case. But you will say that Ireland isn't England and never was and although I find myself unable to subscribe to many human opinions I have in this instance to admit that you are probably right.

I am Sir yours faithfully

April 10th

A HOUGHLINHAM

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

THE House of Commons reassembled on Tuesday April 6th after the Easter recess.

The Special Areas (Amendment) Bill was read a second time.

QUESTION TIME

TUESDAY, APRIL 6TH

The Duties of Coroners

Mr EDWARDS asked the Home Secretary whether in view of statements recently made by coroners which seemed to be outside the function of a coroner he would now consider expediting action on the report of the departmental committee which deplored the tendency of coroners to make animadversions on the character and conduct of individuals.—Sir JOHN SIMON replied: I am not sure what particular statements the hon. Member has in mind but I fear there is no prospect of an opportunity being found during the present session for any legislation on the subject of coroners. I do not think there is any action which can conveniently be taken meanwhile to deal with particular recommendations included in the committee's report; but I have no doubt coroners have noted the recommendation in the report on the point to which the hon. Member refers.

VISCOUNTS AUSTON: Can the right hon. gentleman assure us that some action will soon be taken? Will he bear in mind that it was because of the action of coroners that the committee was set up and that a good many people are beginning to think that the committee was just so much eye wash?

Sir JOHN SIMON: I do not think that the hon. Member can take that view. The committee reported earlier in the year. It is not always possible to legislate immediately when a committee reports. But I would certainly agree with the committee in deprecating animadversions unnecessarily made in the course of an inquest which

reflect on persons who are not in the court and who have no means of reply.

Recruits Below Standard

Miss WARD asked the Minister of Labour whether he had examined the Aldershot experiment in connexion with recruits below the required standard for acceptance in the Army and whether he could make use of the satisfactory results in the sphere of unemployed men who were in need of health services.—Mr. ERNEST BROWN replied: The results of the experiment are now being examined by my department with a view to seeing whether they point to the need for any modifications in the treatment of unemployed men applying for a course of training.

Medicine Stamp Duties

Sir ROBERT BIRD asked the Chancellor of the Exchequer (1) whether he was aware of the great anxiety felt by those members of the Pharmaceutical Society engaged in trade over the recommendations in the report of the Select Committee on Medicine Stamp Duties; and whether it was his intention to introduce legislation implementing the recommendations wholly or in part; and (2) what steps he intended to take for terminating the loss to the revenue consequent upon the avoidance of the payment of medicine stamp duties disclosed in the report of the Select Committee on Medicine Stamp Duties.—Mr. CHAMBERLAIN, Chancellor of the Exchequer, replied: I can assure my hon. friend that due weight will be given to all relevant considerations in connexion with the committee's report but I regret I am unable at present to make any further statement on the matter.

CLATFEBRIDGE ISOLATION HOSPITAL.—A new nurses' home and a cubicle block were opened on March 22nd at this hospital by Major Green, chairman of the Wirral Joint Hospital Board. The scheme cost over £14,000 and the nurses' home has accommodation for 20

OBITUARY

CHARLES COLEY CHOYCE, C M G , C B E ,
F R C S

Prof Choyce, formerly surgeon to University College Hospital and director of the surgical unit there, died in the hospital on Friday last. He had been ill for a considerable time and had retired from all his professional positions.

Charles Coley Choyce was born in Auckland, New Zealand, and educated at the University of New Zealand, where he graduated as B Sc in 1896. He proceeded to Edinburgh for his professional training and graduated in medicine in 1901, proceeding later to the M.D. degree, while in 1905 he obtained the diploma of F R C S Eng. He held resident appointments at the Leicester Infirmary and the Dreadnought Seamen's Hospital, of which institution he was medical superintendent for three years, later he was surgeon to inpatients at the Albert Dock Hospital and assistant surgeon to the Dreadnought, while he also acted as outpatients' surgeon at the Royal Northern Hospital. At the outbreak of war he was appointed consulting surgeon to the Egyptian Expeditionary Force, with the temporary rank of colonel, A M S , he took charge of a large convalescent hospital for officers, and his services were recognised at the close of the war, when he was made C B E and C M G . Shortly afterwards he was appointed professor of surgery in the University of London with the chair at University College, while he became director of the surgical unit at University College Hospital.

We owe to Mr A J Gardham the following appreciation of Prof. Choyce's work and influence. "Prof. Choyce came to University College Hospital in January, 1920, as first director of the surgical unit, a post which he held until his retirement in October, 1935. The post which he was asked to fill was not an easy one—it called for new ideas, for persistence, and for an ability to handle men and things with firmness and tact. All these Choyce had, and by the ungrudging use of them he built up the surgical unit, carried it through its early troubles, and was able, when the time came, to hand it over to his successor as an established institution. It is probably true to say that by the time he came to University College Hospital he felt that his primary interest was in medical education. This interest he followed actively after failing health had curtailed his clinical activities, and it will be as a great teacher and as a charming and courteous personality that Choyce will live in the minds of those who passed through his hands in these years. It was never Choyce's aim to be a figurehead. His contacts with his colleagues and his juniors were essentially personal, and he was perfectly equipped to hold a post which by its very difference from that held by other members of the honorary staff enabled him to act as a connecting link between them. He was never happier than when some surgical or administrative problem led to a friendly meeting of his colleagues in his office. For students he had an almost royal memory, both for faces and character, and it was not for nothing that he was often referred to among them as 'Papa' Choyce. His gentleness however was never sufficiently indiscriminate to include the lazy or the inefficient, and his judgment of men was much more penetrating and critical than he allowed it to appear. The student who worked well in the surgical unit wards however unobtrusively, secured thereby a

wise and helpful friend for as long as he had need of him. The shirker, and most particularly the shirker who laid himself out as he thought to attract the favourable attention of the professor, found a stern critic beneath the genial exterior.

"There can be no one who has acted as Choyce's assistant in any capacity who does not wish to praise him as a master. Once an assistant had gained the confidence of the professor he was left to work out his own lines of thought and action, secure in

C C CHOYCE

the knowledge that his judgment would be backed by his chief in public, even if it were wisely and gently criticised in private. He believed that his function was to train men who would be capable of thinking and acting for themselves when the time came, and consequently his advice was seldom given unless sought. Choyce was sometimes criticised for his apparent inaction in relation to his assistants, and although it is perhaps still too early to judge completely how wise it was, many of those who learned to seek his advice and profit by it are now independent surgeons and teachers who remember their early training with gratitude.

"Choyce's literary activities are well known wherever surgery is practised and the English language understood. Only one who has shared them to some extent can understand the labour which went into the production and re-editing of 'The System'. Nothing but the best was good enough for this book. Choyce rightly felt it to be the standard by which English surgery is judged in many places where it is read of rather than seen, and he was proud of the responsibility which this threw on his shoulders. Personal surgical experience and knowledge which he had in abundance were useful, but not enough. In addition, he had the faculty, born of a very wide association with the leading men of his time, of knowing where to go for what he needed. This, combined with never failing tact and

unremitting labour produced the work of which he was so justly proud. Although it was the best known of his works *The System* was by no means the only one and everything with which he had to deal either as author or editor received the same meticulous attention.

Mr E K Martin writes: When Choyce first came to University College Hospital after the war he was a comparative stranger to its staff and an unknown quantity to the students. The whole time units were just starting in an artificial atmosphere with determination towards their immediate success and doubt as to their ultimate validity. The men returning from the war regarded the intrusion of women into the school with feelings of heat rather than warmth. In the emotional tension of 1919 and within the limited horizons of a medical school Choyce was a monument of kindly permanence. He was confident in his ideals and he liked to help his fellow men. In this sense men included women and his encouragement did much to widen the openings available to them in the hospital. Sympathy with youth was so natural to him that within a few years of his joining UCH he became the recognised confidant of anyone who wanted to talk over or seek advice on the current problems of his life. The annual residents' play never omitted a sympathetic caricature of Papa Choyce. On committees he was a counsellor of moderation and a mediator between differences of opinion. His exceptional capacity for the working out of detail has a permanent memorial in several of the recent buildings and reconstructions at UCH. This same grasp of detail combined with wide knowledge and a gentle power of persuading other people to fall in with his plans made his *'System of Surgery'* the most successful text book of its type in the English language. His surgical work was characterised by a wide knowledge of established procedure and a sound judgment of the men whom he had seen at work.

A friend and colleague of 30 years standing writes: C C Choyce was a man with many friends and no enemies; just the man to edit a *System of Surgery* for he could manage his team without the whip; just the man to run a surgical unit for he had no selfishness, no personal vanity and no axe to grind. He was a sound surgeon of good judgment with no fads or fancies, a sane teacher. His influence on those he taught will spread through the next generation as a healthy leaven.

Throughout most of his time at UCH Prof Choyce's health precluded much work in the operating theatre but with characteristic optimism he made of this disability which he so greatly regretted an opportunity for the encouragement and education of his successors. The courage and equanimity with which he faced the troubles which ill health threw upon him in his later years was the admiration of all who knew even a part of what these were. He was 61 years of age at the time of his death.

Prof Choyce married the daughter of Mr F C Dobbin at Chislehurst who survives him with a daughter and son.

ALEXANDER CORSAIR STURROCK M.D Fdin
M.R.C.P. Lond

THE death occurred at Eccles near Manchester on March 27th of Dr Alexander Sturrock consulting physician to the Salford Royal Infirmary and well known in the neighbourhood as a sound general physician especially well equipped in connexion with

mental disease. A son of the late Mr George Sturrock of Linlithgow he was educated at the University of Edinburgh where he took his degree in arts in 1892 secured a Vans Dunlop scholarship and graduated as M.B. Ch.B. with first-class honours in 1896. On proceeding to the M.D. degree two years later he obtained the gold medal. Having held resident appointments at the Grimsby Hospital and the Manchester Royal Infirmary he started in general practice in Eccles and in 1900 took the diploma of M.R.C.P. Lond. During the war with a commission in the R.A.M.C. he acted as physician to Sir Henry Norman's hospital at Wimereux; later he served for two years at Salonica was mentioned in despatches and retired with the rank of major. He now engaged in consultant work at Manchester and was appointed physician to the Salford Royal Hospital. Here he displayed his practical interest in mental disease organising an out-patients department at Salford in connexion with the county mental hospital at Prestwich.

Dr Sturrock occupied an important social position as a county magistrate, and an active politician with Conservative views. He was 65 years of age at the time of his death.

JOSEPH PEREIRA GRAY M.D Brux M.R.C.S

THE death of Dr Joseph Pereira Gray who died on March 13th in his sixty ninth year removed a much respected and well known figure from the city of Exeter in which he had practised for forty years.

Dr Gray studied medicine at Charing Cross Hospital, London and at Brussels taking the M.R.O.S. Eng. L.R.C.P. Lond. in 1894 and the M.D. degree of the University of Brussels with honours in 1903. He was a prominent figure in Exeter public life holding the appointments of police surgeon, medical officer to the City Hospital and the Exeter Children's Home, medical officer to the Southern Railway and visitor of Licensed Houses under the Lunacy and Mental Deficiency Acts. He was an honorary surgeon to the Exeter Dispensary for twenty five years serving on the committee on numerous occasions and later being elected consulting surgeon. He was keenly interested in ambulance work being the first surgeon to the Exeter City Division of the St John Ambulance which was founded in 1901 and remained its surgeon for very many years, obtaining the long service medal, and being elected honorary life member, lecturer and examiner to the St John Ambulance Association.

A man of untiring energy and with an attractive personality he had a very large general practice his chief characteristic being an unflinching kindness especially to his poorer patients.

GILBERT COCHRANE M.B. Glasg

THE death occurred recently at Birmingham General Hospital of Dr Gilbert Cochrane who had been M.O.H. of the Bromsgrove urban district for the last ten years.

He received his medical education at the University of Glasgow where he graduated in medicine in 1923. He held resident appointments at the Staffordshire General Infirmary and the Consumptive Sanatorium Bridge of Weir and settled in practice at Bromsgrove in 1926 when he was appointed M.O.H. of the Bromsgrove urban district and medical officer for the Bromsgrove Droitwich and Redditch joint isolation hospital. He was also medical officer to the Bromsgrove school and surgeon to the local

cottage hospital. The early termination of Dr Cochrane's professional career is a distinct loss to Bromsgrove and the district. His colleagues on the staff of the Bromsgrove cottage hospital recognised the soundness of his co-operation there, while his work at the isolation hospital was highly thought of by his authority. As M.O.H. of the enlarged Bromsgrove district his duties were carried out in a conscientious manner and marked by a high standard of efficiency.

GEORGE HERBERT SPENCER, M.R.C.S. Eng.

Dr G. H. Spencer, who died at his home at Newcastle after a brief illness on March 24th, practised

on Tyneside for over thirty years, first at Wallsend and afterwards at Newcastle. Born at Austerfield, near Doncaster, he received his medical training at the London Hospital, and qualified with the English double diplomas in 1900. He held resident appointments at the London Hospital and the Tynemouth Infirmary, and was then appointed surgeon to the Hospital for Sick Children at Newcastle on Tyne. Having previously held a commission in the R.A.M.C. (T.A.), he commanded the military hospital at Catterick camp during the war with the rank of lieutenant colonel, R.A.M.C. In the Tyneside he secured by skill and personal popularity a large connexion. He was 67 years of age at the time of his death, and leaves a widow and two children.

MEDICAL NEWS

Royal College of Surgeons of England

On Monday next, April 12th, at 5 p.m., Mr Philip Wiles will deliver his Hunterian lecture which was postponed. He will speak on postural deformities of the antero-posterior curves of the spine. Two Arris and Gale lectures will be given by Dr John Beattie at the same hour on Wednesday and Friday, April 14th and 16th. His subject will be the anatomical and physiological relations of the hypothalamus and pituitary gland.

Society of Apothecaries of London

The May examinations for the diploma of the mastery of midwifery will be held on Tuesday, Wednesday, and Thursday, May 18th, 19th, and 20th, instead of on the dates previously announced.

University of Aberdeen

At a graduation ceremony held on March 31st the hon. degree of LL.D. was conferred on Mr Naughton Dunn, surgeon and lecturer in orthopaedic surgery in the University of Birmingham. The diploma in public health was conferred on Robert Fraser and S. T. G. Gray.

University of Dublin

At recent examinations at the School of Physics, Trinity College, the following candidates were successful—

FINAL MEDICAL EXAMINATION FOR M.B. B.O.H. B.A.O.

Part I

Therapeutics and Pathology—Myer Herman, G. E. Nevill (first-class honours), F. D. F. Steede, Isabella M. Dorman (second-class honours), Thaddeus Fallon, F. H. Counihan, Deborah Bloom, Bernard Kernoff, H. M. Buchanan, M. F. N. Slattery, J. L. Mans, J. W. Cathcart, T. W. Hanna, Jack Morris, Nathan Marks and Mary Conyngham.

Part II

Medicine—William Hayes, H. F. Sloan, O. M. Harrison, Sterling Tomlinson, G. K. Donald, R. W. Duncan, C. J. S. Flood, Rebecca M. R. Pike, H. M. Carson, and F. J. B. Convery. *Surgery*—Ellen D. Maunsell, J. G. Steinbock (second-class honours), P. J. Mullane, Cecil Mushatt, G. C. Retz, D. S. Toole, J. J. B. Convery, J. G. Cunningham, D. J. H. Douglas, P. L. van Aardt, A. J. Reeves, John McQuillan, and Max Levy. *Midwifery*—E. M. Cochrane, G. N. MacFarlane, M. C. Brough, R. E. Taylor, H. J. Walker (first-class honours), W. T. Kenny, J. C. Lambkin, J. E. Gillespie, Stella M. Coen, C. G. Reilly, Charles Cunningham, I. A. Strong, Jasmine Taylor, F. C. Heatley, H. F. T. MacFartridge (second-class honours), M. C. Warneck, F. A. Hanna, A. D. Parsons, Robert Pollock, Jack Freedman, D. G. Harrison, Grace M. Wild, J. N. G. Drury, Patricia M. J. Conway, J. G. Nixon, J. B. Plews, S. G. Heaton, M. G. Wood, J. H. Mitchell, J. R. Steen, Ronald Brass, C. M. Ludlow, and Samuel Rubin.

P.H.H.

Part I—T. A. Austin, Emily M. Booth, H. W. Dalton, and Mary S. Miller.

D.O.O.

Koppel Tatz, M. M. Kriesman, Amla Wassef, and V. D. Lesplasse.

D.P.M.

Part II—H. J. Eustace.

University of Sheffield

At recent examinations the following candidates were successful—

FINAL EXAMINATION FOR M.B. CH.B.

Part II and III—Margaret G. Bell (with first class honours), Ronald W. Elliott, Edmund Schutz, David Shapiro, Ian B. Needon (with second-class honours), Sydney R. Allington, George K. Burton, Harry Cullumhine, Sadallah Khall, Arthur Naylor, Morris J. Pirawer, and George E. Robinson.

Prof Archibald Young and Dr J. G. McCutcheon have been appointed deputy lieutenants of the county of the City of Glasgow.

University of Birmingham

Five William Withering lectures on nutrition and nutritional disorders will be given at the University during April and May. The first lecture will be given by Prof W. N. Haworth, D.Sc., on April 22nd, the next two by Prof J. C. Drummond, D.Sc., on April 29th and May 6th, and the last two by Prof L. G. Parsons on May 11th and 13th. All the lectures will be at 4 p.m. in the medical faculty buildings, Edmund street, and members of the medical profession and students are invited to attend.

Institute of Medical Psychology

Twenty lectures on psycho-physical adaptation will be given at the Institute on Thursdays at 3 p.m. by Dr Hugh Crichton Miller and at 4.30 p.m. by Dr Cedric Shaw from April 22nd to June 24th. Further information may be had from the educational secretary of the Institute, Malet-place, London, W.C.1.

British Health Resorts Association

Next Saturday, April 17th, this association will hold a conference at Skegness. The first discussion will be on Industry and the Health Resort, to be opened by Mr A. L. Peterson, speaking as an employer, followed by Mr Ernest Bevin and Dr L. P. Lockhart. The second will be on Games, Sport, and Sea bathing in relation to Health and the speakers will be Sir Kaye Le Fleming, Dr R. Cove Smith, and Dame Louise McIlroy. The association, whose secretary is Dr Alfred Cox, may be addressed at 199, Piccadilly, London, W.1.

St George's Hospital a New Psychiatric Department

The treasurers of the hospital have received an anonymous gift of £5000 towards the cost of buildings and equipping a psychiatric department in the new hospital. In a letter accompanying the gift, the donor says: "St George's Hospital deserves active public support in its decision to establish a large scale psychiatric clinic. The benefit to patients, staff, and students of making such a clinic part of a general hospital cannot be too strongly stressed."

Mothers' Clinics

The annual Spring Ball in aid of the Mothers' Clinics will be held at Clardge's Hotel on Tuesday, May 18th. Dr Marie Stopes, founder in 1921 of the Mothers' Clinics, will be chairman, and among other members of the committee and patrons are Mr Lloyd George, Mrs Stanley Baldwin, the Duchess of Atholl, Miss Lilian Brathwaite, Dr Harnette Chick, Lady Bertha Dawkins, and Sir Alfred Knox. The tickets are £2 2s each and may be obtained from Dr Marie Stopes, Norbury Park, Dorking, Surrey, Mrs Stallard, 108 Whitfield street, W.1, or from Clardge's Hotel. They cover the cost of the dinner and the buffet, which will be running during the dancing. A cabaret and sideshows have been arranged.

Mr Philip Franklin has been elected hon vice-president of the American Institute for the Deaf Blind

Auxiliary Royal Army Medical Corps Funds

The annual meeting of the members of the funds will be held at 5.15 p.m. on Friday April 23rd, at 11 Chandos street London W

Royal Institution

On Friday April 16th at 9 p.m. a lecture will be given at the institution 21 Albemarle-street London W by Mr T. Macara, F.I.C. who will speak on science and the conservation of food

Queen's University Club London

The spring dinner of this club will be held in the Dorchester Hotel on Thursday April 22nd. Further information can be obtained from the secretaries 101 Harley-street W 1

University of London Medical Graduates Society

The annual dinner of this society will take place in the new buildings of the University at Bloomsbury on Thursday May 6th at 7.45 p.m. The guests of honour will be Mr H. L. Eason, Vice-Chancellor of the University, and Mr W. Gillingham, dean of the faculty of medicine. The annual general meeting of the society will be held before the dinner at 7 p.m. in the University. The society may be addressed at 11 Chandos-street W 1

Ophthalmological Lectures at University of Glasgow

A short course of lectures will be given at 5 p.m. on Tuesdays from April 20th to May 18th at the Tennent Memorial Building Church-street Glasgow. The lectures will deal with leading symptoms in ophthalmology and the lecturers will be Prof. A. J. Ballantyne, Dr. Chesser Macleod, and Dr. John Marshall. All interested are invited.

Preventive Paediatrics

The Association Internationale de Pédiatrie Préventive which is the medical section of the Save the Children International Union, has deferred till September its annual conference which was planned to take place in Rome this Easter. The reason is that the International Child Welfare Congress, which was to have met in Rome at Easter has been postponed to September. The secretary of the association may be addressed at 15 rue Lévrier Geneva.

National Association for the Prevention of Tuberculosis

The King has consented to become patron and the Duke of Kent president of this association which was founded by King Edward VII as Prince of Wales in 1898. The chairman is Sir Robert Philip who fifty years ago established in Edinburgh the first tuberculosis dispensary in the world.

The twenty-third annual conference of the association will be held in Bristol from July 1st to 3rd. The chief subjects for discussion will be propaganda and publicity, methods, preventive institutions with particular reference to open air schools, and the equipment and activities of a tuberculosis dispensary. Further information may be had from the acting secretary-general of the association Tavistock House North Tavistock-square London W.C. 1

Fellowship of Medicine and Post Graduate Medical Association

All-day courses during April and May will be as follows: neurology at the West End Hospital for Nervous Diseases (April 19th to 24th), proctology at the Gordon Hospital (April 20th to May 1st), and psychological medicine at the Maudsley Hospital (April 28th to May 20th). Afternoon courses will be given in dermatology at the St. John's Hospital (May 3rd to 20th) and in thoracic surgery at the Brompton Hospital (May 24th to 29th). Week-end courses will be held in infantile diseases at the Infants Hospital (April 24th and 25th), in cancer at the Royal Cancer Hospital (April 24th and 25th), in chest diseases at the Brompton Hospital (May 8th and 9th), in physical medicine at the St. John Clinic and Institute of Physical Medicine (May 22nd and 23rd), and in children's diseases at the Princess Elizabeth of York Hospital (May 20th and 30th). Further information may be had from the Secretary of the Fellowship, 1 Wimpole-street W.

A Congress on Hormones

The Journées médicales internationales de Paris will be held from June 26th to 30th under the patronage of the *Revue médicale française*. The subject for discussion will be the biological, clinical and therapeutic aspects of hormones. Prof. Paul Carnot will preside and the secretary-general is Dr. Godlewski.

National Institute of Industrial Psychology

After considering what steps should be taken to cope with the increasing work of this institute the council has appointed Mr. T. G. Rose, M.I.N.E.E. general director. He will collaborate with Dr. C. S. Myers, F.R.S., the principal who will retain the position held by him since the institute opened 16 years ago. The address is Aldwych House Aldwych London, W.C. 2.

King's College Hospital

During the evening service at 5.30 p.m. on Sunday April 18th a plaque will be unveiled in King's College Hospital chapel to the memory of Dr. Harold Wiltshire formerly one of the physicians to the hospital. At the same service the endowment of a bed in memory of Mr. Albert Carless who was actively associated with the medical school and hospital for nearly 40 years will be offered by his wife. The address will be given by his friend the Rev. Howard Banister vicar of Wallington Surrey.

Progress of Cremation

In the annual report presented to the Cremation Society recently it is stated that whereas ten years ago there were 16 crematoria with 2877 cremations the numbers last year were 33 and 11,289 respectively. The society whose headquarters are at 23 Nottingham place London W 1 conducts propaganda in favour of cremation and makes arrangements for registration of the desire to be cremated and for assurance against the cost. The International Cremation Congress is to be held for the first time in England this autumn meeting in the Guildhall London from Sept. 24th to Oct. 2nd. The National Association of Cemetery and Crematorium Superintendents holds its twenty-second annual conference at Torquay from June 28th to July 1st.

Rate Burdens on Hospitals

Emphatic protests against the crushing burden of rates on voluntary hospitals, coupled with appeals from the various institutions for a system of differential rating were made at the recent annual meetings of the Brighton hospitals. It was stated at the court of governors of the Royal Sussex County Hospital the largest hospital in the town that 6s. in every £ received in subscriptions had to be paid away in rates, and the other institutions had similar experience in 1936 in proportion to their size. At the annual meeting of one of the hospitals the mayor defended the position by stating that the law forbade the authorities to do anything in the way of differential rating. Brigadier-General d'A. C. Brownlow chairman of the governors of the Royal Sussex County Hospital, replied to this statement by giving figures regarding the rating of hospitals in other parts of the country and asked for an explanation of the difference. He found he said that the 1650 beds in Sussex hospitals were valued at an average of £7.13. In the adjoining counties, including Canterbury, Tunbridge Wells, Guildford, Winchester, Portsmouth, and Southampton, 1574 were rated at £3.64 per bed. Further afield at the large hospitals of Bristol, Birmingham, Hull, Liverpool and Sheffield 6995 beds were rated at an average of £1.81. This the chairman said showed that some rating authorities had found a way of giving preferential treatment to their voluntary hospitals. Replying to a suggestion that the corporation be asked to return the rates in the form of an annual donation if it were impossible to reduce the assessment he said the authorities had power to contribute to hospitals up to 1.2d. in the £. The governors had never asked the corporation to make such a donation and it had never been volunteered. He added that he believed Portsmouth returned the whole of the rates in the form of a grant.

Queen's Hospital for Children Hackney-road, L—H.S. at rate of £100. Also Clin. Asst. for Med. Out-patient Clinics 6s. per attendance.

Reading Royal Berkshire Hosp—H.S. Cas. O also H.S. to Spec. Depts. each at rate of £150

Rochester St. Bartholomew's Hosp—H.S. at rate of £150

Rochester Hosp—Hon. Anesthetist

Royal Chert Hosp City road E.C.—Res. M.O. at rate of £150 also Med. Res.

Royal College of Physicians Pall Mall East S.W.—Proprietor Scholar £100

Royal Free Hosp. Gray's Inn road, W.C.—Asst. Physician to Dept. of Physical Medicine. Also Res. Asst. Pathologist

Royal Naval Medical Service—M.O. A.

Royal Northern Hosp. Holloway A.—H.S. at rate of £70

Royal Waterloo Hosp. for Children 40, Waterloo-road, S.E.—H.S. Cas. O and H.P. at rate of £150 and £100 respectively

Salisbury General Infirmary—H.S. M.O. £250

Sheffield Children's Hospital—H.S. at rate of £100

Sheffield Jessop Hosp. for Women—H.S., at rate of £100

Sheffield Royal Hosp—Clin. Asst. to Ophth. Dept. £300

Sheffield University Dept. of Bacteriology—Asst. Bacteriologist and Demonstrator, £500

Shrewsbury Royal Salop Infirmary—Res. H.P. at rate of £150

Stearns Metropolitan Borough—Deputy and Asst. M.O.H. £750

Sunderland Royal Infirmary—Cas. O £150. Also two H.S.s each £150

Surrey County Council Mental Hospital's Service—Jun. Asst. M.O.s each £250

Swanley, Kent, Hosp. Convalescent Homes Parkwood—Res. M.O. at rate of £200

Swansea Adeline Hall Hosp—H.P. at rate of £150

Swansea General and Fyfe Hosp—Cas. O at rate of £150—£175

Swindon Borough—Deputy M.O.H. and Asst. School M.O. £600

Taxford and Somerset Hosp—H.S., at rate of £100

Torquay Torbay Hosp—H.S. and H.S. each £175

Victoria Hosp. for Children 211e-street S.W.—Cas. O at rate of £200

Wallasey Victoria Central Hosp—Jun. H.S. £150

W. Cam. Bromwich Hallam Hosp—H.P. at rate of £300

Western Ophthalmic Hosp. Marylebone road, W.—Jun. Res. H.S. £100

Westminster Hosp. Broad Sanctuary S.W.—Asst. M.O. in X-Ray and Electrical Dept.

Willesden General Infirmary—H.S. at rate of £250

Wickford Essex Torquay Hosp—Asst. Res. Physician £350

Windsor Royal Hampshire County Hosp—H.S. at rate of £150

Wolverhampton Royal Hosp—H.S. each at rate of £100

Woolwich Arsenal Memorial Hosp. Shooter's Hill, S.E.—H.P. and H.S. each at rate of £100

York Dispensary—Res. M.O. £175

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Newport (Monmouth), Edgware (Middlesex), Paisley (Renfrew), Kilmid (Renfrew), and Ayr (North Ayrshire).

Medical Referee under the Workmen's Compensation Act 1925 for the Dewsbury, Leeds, Otley and Wakefield County Court Districts (Circuit No. 14). Applications may be made to the District Private Secretary, Home Office, Whitehall London S.W. 1 before April 26th.

Tuesday, April 13th—4.15 P.M. Dr A. Ham: 1 item Infections of the Gall bladder

Friday, April 16th—11.30 P.M. Dr H. Newell: Demonstration of Surgical Cases

GLASGOW POST GRADUATE MEDICAL ASSOCIATION
Wednesday, April 14th—4.15 P.M. Lect. at Hospital Dr David Watson: Venereal Disease in Women

NOTES, COMMENTS, AND ABSTRACTS

MUSIC IN THE FACTORY

(BY AN OCCASIONAL CONTRIBUTOR)

IN tackling seriously the subject of boredom in industrial workers the Industrial Health Research Board¹ has undoubtedly come to grips with one of the major problems of modern life for here, at bottom, lies the secret of strikes, revolutions, wars and the rumours of wars. The bulk of humanity have had to sell their birthright for a mess of pottage and no wonder they have proved fractious and discontented bargainers. The replacement of craftsmanship by mass production has bereft many of the individuality which was a sufficient compensation for poverty. The carver of Chippendale chairs or the moulder of Chelsea figures had probably to work long, hard and for little gain, but he had also the never failing satisfaction of seeing his own work and of knowing that it was good.

The investigations dealt with in a recent report on boredom in repetitive industry are conceived on the simple lines no doubt essential in the preliminary study of such a complex problem as this. The subjects of the investigations were four groups of factory girls working at chocolate packing, cracker making, and "tying small blocks in calico." These jobs are no doubt deadly dull, but not more so than those which engage the majority of factory workers. A short questionnaire was devised, the answers to which were calculated to give some general idea of the psychological reactions of the worker to her work. The outcome of the inquiry can be anticipated, but it is none the less pitiable. Of 355 workers, only 3 per cent expressed no sign of boredom, 83 per cent were slightly affected, 38 per cent experienced a moderate degree, and 26 per cent suffered severely. Temperamental differences accounted for a good deal of variation in the amount of boredom suffered, and, understandably enough, the more intelligent type of worker suffered most severely. It is possible that women, who look elsewhere than in hired work for the fulfilment of their lives, suffer more than men, but many of them have their day-dreams for compensation. Men on the other hand are more given to kicking against the pricks and they shoulder their burden knowing it will stay with them while health and life last. The writers of the report study many causes of discontent among workers. Questions of promotion, security, supervision, wages, hours of work, &c., have all their contributory effects, but the radical remedies for these are matters too inflammable to be the subject of official reports. The investigators make, however, one valuable positive contribution to the prevention of boredom in industry. They found that gramophone records played at chosen periods during the day had a marked alleviating effect on the symptoms. Almost all the workers, we are told, "responded to the music by an increased output." The average increase in output while the music was actually being played was 6.2 to 11.3 per cent.

An inquirer of another age might well wonder why the ingenuity of psychologists could not have devised a more delicate test for human contentment than an increased output of chocolate boxes, but we are in a century when the still small voices of humanity are liable to be drowned in the clash of machinery and the rattle of cash registers. Music the antidote to misery—an old theme with ever new application! The caged linnets sing away its captivity. The chain gangs and the galley slaves sang their rhythmic

catches as they strained and sweated. The old mariners found their shanties helped them to weigh the anchor and to endure their hardships. The negroes in the cotton fields, no doubt, increased their output in bales with their plantation songs and the Volga boatmen who, if music and elementary geography go for anything, lived a hard and bitter life, probably got a 10 per cent increase in speed by singing their stirring boat-song. But now when division of labour is an inexorable law and the discipline of the factory has advanced beyond that of the chain gang, the music too is no longer individual but must be provided by mechanical devices.

There is music like the Liebestod from *Tristan* or the last movement of the Fifth Symphony which must be received head between hands and in semi-coma. The investigators who, no doubt, had shareholders to consider made no experiments with this kind of music. Of the types they tried "light orchestral music" seems to have had least effect and this we take as welcome evidence that our factory girls, though sore beset, have still sturdy souls. It was the youthful and stimulating music which goes by the name of "jazz" or "rhythm" that was found to be the best antidote to boredom. "It is generally agreed" say our investigators gravely, "that rhythm induces a pleasant emotional effect which acts as a more favourable background for production." But we should like to have more precise details as to the nature of the successful music. The investigators give the impression that a studious and sheltered life may have made them insensible to the finer distinctions of rhythmic music. It is not enough to classify their records as waltzes, one-steps, or fox-trots. There are fox-trots and fox-trots, and dance bands and dance bands, and of this an industrial psychologist could convince himself if he compared the incomes of the "kings of jazz." Is the output as great with the music of Duke Ellington as with that of Irving Berlin? We can imagine shuffling chocolates to Ellington's nocturnal measures, but not packing them. The astute psychologists of Radio-Normandie seem to find that the Blue Danube and the Lily of Laguna, old as they are, have a specially potent effect in helping mothers of families through their daily chores and in keeping them diligently dosing their children with vitamins, laxatives, and antacids. The Blue Danube may suit the mangle vat fail with "tying small blocks in calico." There is obviously a field for further inquiry here and the services of Mr. Charles Cochrane, Mr. Ambrose, or Mr. Roy Fox might be advantageously co-opted for the investigation.

But, when all is said, this question of boredom in the modern world is a desperately serious and important affair and well worth the continued attention of the Industrial Health Research Board. There is much to be done and it is satisfactory to see that a good start has been made. The medical man, himself a worker who, whatever his misfortune, rarely knows boredom, may well be moved, by the picture given in this report of the soul under the industrial system, to see, as it were, the naked nerve touched by the experimenter's probe. But let us look back too regretfully to the simple life of the old world, let us quote from another observer as impersonal as the writer of government reports and infinitely more callous—

"certains animaux farouches, des mâles et des femelles répandus par la campagne noirs, livides et brûlés du soleil attachés à la terre qu'ils fouillent et qu'ils remuent avec une opiniâtreté invincible ils ont comme une voix articulée, et quand ils se lèvent sur leurs pieds, ils montrent une face humaine et en effet, ils sont des hommes."

And there were no gramophones, radios, cinemas or football pools under the old regime.

¹ Fatigue and Boredom in Repetitive Work. By S. Wyatt and J. N. Langdon (assisted by F. G. L. Scott). Medical Research Council Industrial Health Research Board. Report No. 77. H.M. Stationery Office. 1937. Pp. 77. 1s. 3d.

mothercraft ranging from the onset of pregnancy to the character training of toddlers. It is essentially a practical book and the author does not theorise, but in places it is perhaps too complicated and full of alternative suggestions for the average mother or child's nurse, but monthly and welfare nurses, for whom also presumably it is written, will not find this a defect. In the chapter on infant feeding it is surprising that whereas such things as peptonised feeding are described in some detail no mention is made of lactic acid milk. Excellent emphasis is laid upon the importance to the infant of fresh moving air and the correct balance of rest and exercise. The last few chapters are devoted to a discussion of childish ailments, accidents, and illnesses, and contain much sound advice. There is a chapter dealing with the care of infants in the tropics, a short bibliography, and a good index.

We are informed that nearly two hundred thousand copies of this book have been sold, it remains one of the best of its kind.

MEDICAL ACTIVITIES FOR LAY READERS

THE increasing popular demand for superficial knowledge on various topics fostered by certain organs of the press and not altogether discouraged by the B.B.C. has produced a spate of small books of which a typical example is one entitled *Science Fights Death*. Herein the progress and problems of modern medicine are thinly though not inaccurately discussed in non-technical language. Bacteriology and infectious diseases, parasitology, virus diseases, the endocrines, plastic surgery, industrial and blood diseases and the cancer problem are some of the things touched upon, the author is to be forgiven if he has chosen the more cheerful and dramatic themes, for it is well known that laymen are always more interested in the potentialities of a subject than in its limitations. Moreover, the doctor lured, however unwillingly perhaps, at a dinner-party to talk about his job, might do worse than take this book as a model of how to "put over" snippets of information in a manner calculated not to bore the casual listener.

NEW PREPARATIONS

ACROSONE—The advantages claimed for this antiseptic are that it is neither poisonous, irritating, nor corrosive, giving a relatively clear solution in water and having a Rideal-Walker coefficient of 13. It is slightly oily, and thus discourages adhesion of dressings to wounds. For the sterilisation of instruments immersion in a 20 per cent solution for ten minutes is said to suffice. The use of Acrosone is also advised for cleaning septic wounds, for vaginal douching for sterilisation of hands and skin for rinsing ulcerated mouths, and for treating cutaneous sepsis. It is made by James Woolley Sons and Co., Ltd., Victoria Bridge Manchester 3.

BILRON is a mixture of iron and bile acids in the form of ferric bile acids. It is soluble in alkaline solution, but almost insoluble in water and acid media and it may therefore be taken by mouth without special enteric coating. Its administration is suggested wherever stimulation of secretion of bile is desired—e.g., in dyspepsia due to hepatic insufficiency and in some forms of constipation and of migraine—and also during surgical drainage of the biliary tract. The manufacturers of Bilron (Eli Lilly and Co., Ltd., 2, Dean-street, London, W 1), refer to unpublished observations by Kohlsaadt and Rosenak on the usefulness of iron bile salts in cases of cholecystitis without stones. The product is sold in 5 grain Pulvules (filled capsules).

SOLUSITASIN a product of Pharmaceutical Specialities (May and Baker) Ltd., Dagenham, is disodium *p* (4-phenylpropylamino) benzenesulphon-

amide- α , γ -disulphonate. It is supplied in ampoules in 5 per cent solution and recommended by the makers for intravenous or intramuscular injection in the treatment of severe streptococcal infection.

VITEOLIN is the name now given by Glaxo Laboratories Ltd. (Greenford, Middlesex) to their wheat-germ oil extract. They have issued a booklet entitled "Vitamin E" which gives an account of the clinical use of this vitamin especially in the treatment of repeated and threatened abortion. The extract is described as a twenty-five fold concentration of the vitamin E in wheat-germ oil, and it is put out in 3-minim capsules.

ORHEPTAL—E. Merck, of Darmstadt, have prepared a new tonic for use in cases of secondary anaemia, during convalescence and in conditions of weakness and loss of tone. Besides a concentrated liver extract, it contains ferric ammonium citrate, cupric chloride, tincture of nuxvomica, sodium and manganese glycerophosphate, caffeine, and small quantities of quinine, bitters, alcohol, and syrup. It is obtainable in this country from Savori and Moore Ltd., 61, Welbeck-street, London, W 1.

A pamphlet on "Ovarian Hormones in Clinical Practice" is issued by BOOTS PURE DRUG CO. LTD. (Nottingham). It gives particulars of the Boots preparations of oestrone benzoate (Ovostab) and corpus luteum hormone (Luteostab) and illustrates the use of these substances by quotations from published papers.

WANTED, A CASE OF BILIARY FISTULA—MR. ABERD, who is investigating the effect on the liver secretion of various medicinal waters, would be glad to find a case of biliary fistula willing to undergo such a test. All expenses would be paid.

Births, Marriages, and Deaths

BIRTHS

- AMUD**—On April 4th at Blackpool the wife of Dr J. Wilson Aird of a son.
BLACK—On April 1st 1937 at Leeds to Stella wife of George Black, F.R.C.S. of 26 Park square, Leeds—a son.
CONSTAD—On April 3rd at Welbeck street W, the wife of Dr Victor Constad of a daughter.
DANNATT—On March 24th, at the Middlesex Hospital, W the wife of Mr R. M. Dannatt F.R.C.S. Eng. of a son.
HARTLEY—On March 29th at Rye, Sussex the wife of Dr J. L. Hartley of a daughter.
JAMES—On March 25th the wife of T. G. Illyd James F.R.C. of a son.
JOHNSTONE—On April 2nd, at Leicester the wife of Mr A. Johnstone F.R.C.S. Edin. of a daughter.
McCONNEL—On April 2nd at Welbeck street W the wife of Dr R. W. McConnell, Wendover, Bucks, of a son.
TURNER—On March 23rd at Bracknell Berks the wife of Dr Ronald Turner of a son.

MARRIAGES

- BETTFY-SANDERS**—On March 31st at St. Peter's, Croydon F. Ray Bettfy M.D. of Croydon to Mary Stewart only child of Robert Stewart Sanders formerly of Parley.
BOWES-WHITTON—On March 31st at the Church of the Annunciation, Bryanston street W. Robert Wallace Bowes M.A. M.R.C.S. of Miss Norfolk to Gen. Mary Whitton M.Com. (Vict.) Seymour street London W.
LANGTON-WHITE—On April 3rd at St. Mary's Church Scarborough Peregrine Stephen Brackenbury Langton M.B. Medical Superintendent of the Royal Earlswood Institution Redhill Surrey to Vera Dennis White young daughter of Mr F. A. White of Scarborough.

DEATHS

- BRISCO OWEN**—On March 24th Ella Gertrude Brisco-Owen L.M.S.A.
N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

ADDRESSES AND ORIGINAL ARTICLES

POSTURAL DEFORMITIES OF THE
ANTEROPosterIOR CURVES OF THE
SPINE *

Dr PHILIP WILES M.S. Lond. F.R.C.S. Eng
ASSISTANT ORTHOPÆDIC SURGEON TO THE MIDDLESEX
HOSPITAL, LONDON

The generally accepted views of the physiology of the neuromuscular system so far as they concern posture have undergone considerable modification of recent years. Before discussing them however it is necessary to emphasise a fact that should be a commonplace—the ligaments play no part at all in the normal regulation of posture. Over a hundred years ago Delpech (1828) a French orthopædist drew attention to this fact, but its general acceptance has been very slow. The function of ligaments is to limit the extremes of movement, and no loss of stability need occur when they are absent as may be seen after complete excision of the capsule of the hip joint.

The function of skeletal muscles is to cause movement and to maintain posture but an individual muscle fibre is capable only of one thing the development within itself of a state of tension. Its behaviour when the tension develops depends on conditions external to itself. If there is no resistance to its movement, the fibre contracts. If there is resistance which it is unable to overcome movement is absent or minimal and the contraction is said to be isometric. The former process is used in making movements the latter in maintaining posture. Individual fibres appear to follow the all or none law so the power exerted by a whole muscle is proportional to the number of fibres in action. This in turn depends on the external resistance to be overcome and the rapidity of the movement consequently for the maintenance of posture the number of fibres required at once may be very small.

Each muscle-fibre or small group of fibres is separately supplied by motor nerves which can transmit impulses of only one type and in one direction. For the purpose of maintaining posture muscular power and therefore the number of fibres in use at once is comparatively small so that continual change of contracting fibres can occur and fatigue is reduced to a minimum. This is clearly shown in records of the action currents which are produced during the active contraction of a muscle. A fine double electrode is inserted into the substance of the muscle the current is amplified made visible by means of a cathode ray oscillograph and photographed on a moving film. The currents are of a moderately small order and only such as are produced by muscle fibres in the immediate neighbourhood of the electrode are detected. Dr C. A. Keeler of the department of physiology at the Middlesex Hospital Medical School, has been kind enough to assemble the apparatus and coöperate in making a number of observations.

In Fig. 1 are records of action currents in the central portion of the gluteus medius. When the leg was supported so that the muscle was completely relaxed action currents were absent or only occasionally recorded (above). When the subject was standing with both feet on the ground so that the muscle was engaged in maintaining normal upright posture, contractions were fairly frequent but not absolutely

regular (middle). During active muscular contraction violent activity is recorded (below).

The process of maintaining posture requires the balanced contraction of the muscles on each side of the joint concerned—that is in the upright position nearly every joint in the body. The regulation of this complicated process is entirely a function of the central nervous system. It is brought about mainly

FIG. 1.—Action currents of central portion of gluteus medius. Above: leg supported and muscle fully relaxed. Middle: standing still with legs 6 in. apart. Below: standing on one leg.

by means of unconscious reflexes which coordinate afferent impulses from the muscles joints eyes ears and skin.

A permanent change in habitual posture is not maintained by the muscles on one side of the joints concerned contracting more strongly whilst those on the other side are more relaxed. This process only causes the movement by which the new posture is reached. Once it is reached, all that is necessary to maintain it is a change in the length at which the muscles must remain and the power required may be no greater than before. To keep the muscles habitually at this changed length is obviously a function of the central nervous system and involves the conditioning of a new reflex which regards a new muscle length as normal.

The requirements for a good posture in an otherwise healthy body are adequate muscles and correctly conditioned reflexes. The muscular power required to maintain posture is so small that it is unusual for muscular weakness alone to be the cause of postural deficiency. In a large proportion of cases the error lies in the postural reflexes and it is to this that attention has chiefly to be directed. It is perhaps permissible to compare the state of affairs to that in a pianola. When a record of a given pattern is passed through the instrument a particular tune is played but it is subject to the conscious modulations of the player by means of the speed and volume controls. Any fault in the record will be reflected in the tune and can be remedied only by altering the record conditions in the body are much the same. Temporary modification of posture can be obtained by conscious control but any permanent change must be associated with an alteration in the postural reflexes. Increasing the size and power of the muscles alone will have no effect.

Ætiology

The causes which lead to the development of faulty postural reflexes, or to a change from good to faulty reflexes, are little understood. There must be many factors concerned, more than one of which are likely to be present in any case.

A great number of postural deformities commence in late childhood and adolescence, during periods of rapid growth. The bones and muscles are then increasing in length and the central nervous system is continually being called upon to modify its postural reflexes. This adjustment is likely to be interfered with by any upset in general well being. There are many ways in which this can be brought about, at the present time a common one is undernutrition. Toxæmia from some chronic infection is another factor which may play its part, and one which is itself greatly aggravated by undernutrition.

It is doubtful if heredity is concerned in the ætiology of those cases falling within the definition of postural deformities, but it is probably of importance in certain of the fixed deformities which cannot be corrected by voluntary muscular effort, for example, those "malignant" cases of pes cavus or of scoliosis which tend to recur or to progress in spite of every treatment.

It has been the custom of surgeons for many years to blame the immediate surroundings of the patient, such as vicious school furniture and types of clothing, for the onset of some deformities. Some have even gone so far as to suggest that "one sided" occupations, like violin playing and the use of a side saddle in horse riding, are sometimes responsible for scoliosis! No logical explanation of the mode of action of such mechanical factors has been brought forward and it is difficult to believe that they are of any great importance. A child who is determined to sit badly will do so at any desk—it would be far more rational to blame a boring lesson that fails to hold his attention.

A normal posture can only be assumed when the higher parts of the brain are intact, so it is reasonable to suppose that any disturbance in the normal functioning of the brain can interfere with the development of postural reflexes. It is obvious that posture is subject to conscious modification, and, by analogy, it might be expected to be influenced by unconscious cerebral processes. There is a growing tendency to explore the psychogenic factors underlying disease processes of many sorts. The investigation of this subject is fraught with the greatest difficulties, and there are many pitfalls in the way of the interpretation of any findings. Sometimes, however, it does seem possible to make a direct correlation between the psychopathological findings and the physical condition, and certain cases of postural deformity provide excellent examples.

Brinkart has said "to diagnose a scoliosis, look at the child's back, to find its cause, look at the mother's face." The general truth of this observation is apparent to everyone and, moreover, it is quite rational to expect that any psychological maladjustment will be reflected in the postural habits. The most extreme case of the association of an abnormal psychological state with an abnormal posture is seen in "neurasthenia" using the word in its narrow sense of a particular functional nervous disorder. It occurs in both adults and children, and the picture is very distinctive. The patient is flabby in both body and mind. Mentally he is tired, bodily he has given way to gravity and has sagging jaw and eyelids, tilted pelvis, and flat feet. The mental and

physical conditions go together and any attempt to change the physical condition, until such time as the psychological adjustment has been improved, usually leads to disappointment.

Other but less clearly defined groups are to be found amongst children and adolescents. In the "anxiety states" the general picture is of a hyper-sensitive, alarmed child, not infrequently subject to nightmares and often with a stammer. Physically he tends to have flat feet, knock knees, and round shoulders, a position of fear, but, in contrast to the "neurasthenic," his muscles are tense rather than slack. Again, the "obsessional" child may show queer habits of gait and posture, often asymmetrical which are impossible to explain except in association with the psychological condition.

To sum up, there are a number of factors concerned in the ætiology of postural deformities. The most important are undernutrition, rapid growth, and psychological maladjustment. Undernutrition alone may provide sufficient cause by undermining the general health, both physical and mental. In other cases it develops during a period of rapid growth in people who are emotionally disturbed, and consequently are unable to make satisfactory adjustments in their postural reflexes that are necessary to meet the needs of growth. In a further class, exemplified by the "neurasthenics," the psychological attitude is directly reflected in the posture. I do not maintain that nearly everybody with a postural deformity is a "neurotic." I suggest rather that, in far more cases than is usually suspected, there is some psychological maladjustment that interferes with the development of correct reflex postural habits. The maladjustment is often only temporary, and, when it has corrected itself, the postural habits also are readily corrected.

Pelvic Inclination

Deviation of the curves of the spine from what has come to be regarded as normal is of more than cosmetic importance. It reduces the mechanical efficiency of the back so that it is more readily fatigued and more liable to strain. It is therefore important to have accurate knowledge of the normal arrangement, and some method of mensuration more accurate than the usual one of judging by eye is desirable. Direct measurements have proved notoriously unsatisfactory because of the difference in the thickness of the fleshy and fatty coverings and of the actual lengths of the spinous processes. The ideal method of measurement would be to take radiograms of the standing patient with a tube at 6 ft and a plate large enough to cover the pelvis and most of the spine. A suitable X ray apparatus is in existence, but, as it is not available in this country even for research work, the method is at present of no value for routine use.

Since it is impracticable to measure the spinal curves directly, attention has been turned to an indirect method. The spine is attached to the pelvis at the lumbosacral junction, so that any movement of the pelvis will cause a corresponding movement of the fifth lumbar vertebra. The habitual posture of the pelvis therefore determines that of the fifth lumbar vertebra, which in turn must affect the posture of the whole lumbar spine. Hence measurement of the inclination of the pelvis should give a estimation of the curve of the lumbar spine.

The inclination of the pelvis has never been measured satisfactorily in the living subject. Reynolds and Lovett (1910) say they believe it to be impossible to measure its variations with sufficient accuracy.

to be of value, but they give no indication of the methods they have tried. Most estimations have been on the cadaver but several workers, notably Prochownik (1882) have attempted it on the living subject by rather elaborate means.

I have devised a simple method of measuring the pelvic inclination which I believe is of sufficient accuracy. Measurements of the inclination of a fixed object give readings accurate to 1° with different observers. Repeated measurements of the pelvis of the same people on different occasions gave a variation of $\pm$ or -2 . This wider variation is accounted for by a slight difference in posture on the different occasions and it is not present if the person stands still whilst several observations are made.

The instrument (Fig. 2) has been made for me by Messrs. Down Bros. Ltd. It consists essentially of a pair of external callipers with a vertical plate fixed at the hinged end in such a way that it is always in a plane at right angles to the plane of bisection of the callipers. The plate is graduated in degrees, and a plumb line suspended so that the inclination to the horizontal can be read directly from the scale.

The points taken for measurement are the upper border of the symphysis pubis in front and the level of the posterior superior spines behind. This posterior level was chosen rather than the fifth lumbar spine

blade adjusted to touch this point. The left blade is placed on the mark already made posteriorly. Finally the graduated plate is made parallel with the plumb line and therefore vertical and a reading is made.

Lovett (1931) quotes the figures for the pelvic inclination obtained by various investigators in the

FIG. 3.—Pelvic inclination of adults. Males (interrupted line) average 31. Females (continuous line) average 28.

last century as ranging from 41 to 65 . He says that all the figures are adjusted to give the inclination of the true conjugate of the pelvis which he defines as the line joining the lumbosacral junction to the upper border of the symphysis. However, Ten Teachers Midwifery (1935) defines the true conjugate as the line joining the centre of the promontory of the sacrum to the nearest point on the surface of the symphysis. The planes in which these two lines lie differ by some 10° so it is difficult to use Lovett's figures as a basis for comparison. Prochownik (1882) has adjusted his figures to give the inclination of the plane of the pelvic inlet and thus differs from both the above planes.

The older workers were interested in the inclination of the pelvis from the point of view of the mechanics of parturition. Since this is not now the only interest, and since the inclination of the true conjugate can only be measured directly by radiography I suggest that this plane should no longer be used as the standard. Subsequent mention in this paper of the inclination of the pelvis will refer to the angle between the horizontal plane and the plane of the lines joining the posterior superior spines to the symphysis pubis.

The pelvic inclination has been measured in a consecutive series of normal adults. The women were mostly nurses and massage students aged 18 to 30 (average 21). The men were from a V.M.C.A. training class and medical students aged 17 to 30 (average 23). The figures are given in the Table and the frequency with which the various inclinations occurred is shown in graphic form in Fig. 3.

Table showing Pelvic Inclination

	Average.	Range
93 men	31	3–19
137 women	28	35–18

FIG. 2.—Pelvic inclinometer

because the latter is much broader and often difficult to palpate accurately. No mention of posture is made to the subject unless the one adopted is obviously forced. The posterior superior spines are palpated and a pencil mark made on the skin at this level in the midline. The blades of the callipers are held one in each hand with much the same sort of grip as a pencil is held when writing. The upper border of the symphysis is palpated with the middle finger of the right hand and the point of the right

It was necessary to discover to what extent the shape of the lumbar spine would correlate with the pelvic inclination. With this in view a note was made in every case of the appearance of the back as judged by eye and of the degree of lordosis so far as it could be measured. This was done by dropping a plumb line from the most prominent vertebra and measuring the distance in inches from the plumb line to the sacrum and the point of maximum lumbar convexity.

It was found that these measurements were almost useless as a guide to the shape of the spine. The appearance, however, was of much greater value and correlated well with the pelvic measurement.

The normal curves of the spine must vary a certain amount from individual to individual, and it is very difficult to define them. Moreover, if a person is leading an ordinary life and is free from symptoms, it is difficult to say that any small deviation from an arbitrary standard is abnormal. The standard here adopted is one in which the body is well "set" as judged by the eye, and in which a vertical line in the plane of the mastoid process passes through the middle of the shoulder and hip joints, towards the front of the knees, and well in front of the ankles (Fig 4). By this standard, 56 per cent of the men and 46 per cent of the women in this series were classed as having normal curves and normal posture. The pelvic inclination in the men ranged from 34° to 26°, with an average of 31°, and in the women from 33° to 23°, average 29°. Individuals classified as having a lumbar lordosis invariably had an increased pelvic inclination, and those with a flattened lumbar spine had a decreased inclination. A change in inclination also occurred in those who leant backwards or forwards at the hips and yet had normally curved spines, and in certain other abnormalities of posture. This will be discussed more fully under types of postural deformity.

It is usually said that the posture and spinal curves vary with the type of body build. With a view to studying this point, the type of each person examined was recorded. The classification used was normal, sthenic, asthenic, and dysplastic. The standard of normal was again an arbitrary one and really amounted to the mean between sthenic and asthenic. Individuals with a sthenic lower body and asthenic thorax, or vice versa, were described as dysplastic. These types have

been carefully correlated with the rest of the data. No particular type of posture or spinal curves could be found corresponding to the body types. The average angle of pelvic inclination of each type closely approximated to the general average.

The pelvic inclination is rather smaller in the early years of life than in the adult. This is as might be expected during development from the flexed intra-uterine position to an upright posture. An attempt

FIG 5.—Pelvic inclination of children. Males = continuous line. Females = interrupted line.

has been made to follow this change statistically, but difficulties were experienced in obtaining access to a sufficient number of children. The education committee of the London County Council kindly gave me permission to attend the routine medical examinations of children under their control. These examinations are made at approximately the ages of 4, 7, 11, and 13 years, and twenty-five children of each sex at each of these ages were measured. The results are given in Fig 5 and suggest that there is a steady increase in pelvic inclination up to the age of 11 when the adult level is reached.

Muscular Control

The pelvis is balanced on the femora, so that its angle of inclination (and consequently the curve of the lumbar spine) depends on the posture of the hip joints. The muscles controlling the hips are therefore responsible for determining the pelvic inclination. In the upright position the thighs are the fixed points from which these muscles act, so that contraction of the flexors (the iliopsoas and rectus femoris) will increase the inclination, and contraction of the extensors (the glutei and hamstrings) will decrease it.

Investigation of muscle action by means of their action currents has brought out two points concerning the glutei that are of importance. It is commonly stated—e.g., Quain's Anatomy (1923)—that the *gluteus maximus* is not used in ordinary walking movements to any great extent. This could not be confirmed. The muscle participated in producing full external rotation of the hip and in every movement involving extension, including tilting backwards the pelvis. The *glutei medius et minimus* are primarily abductors of the hip but they are also extensors and, by their central and posterior portions, they are external rotators.

The three glutei function in life as one unit and as part of the extensor group of muscles that maintain the upright position. Their combined action on the hip can produce extension, abduction, and external rotation, but the thigh or pelvis is moved according to which is the fixed point. Postural increase in the

FIG 4.—Normal posture. A line has been drawn through the mastoid process parallel to a plumb line included in the original photograph.

lengths of these muscles will therefore result in forward tilting of the pelvis and internal rotation of the legs. The latter is of considerable importance in the aetiology of flat feet.

The action of the *rectus abdominis* is often misunderstood because it can be seen to contract synergically with the glutei when the lumbar spine is flattened. From this it is often argued that the rectus and not the glutei is tilting the pelvis backwards and consequently remedial workers pay great attention to it in cases of lordosis. However such an action is impossible because there is no fixed point above from which it can pull.

If the *rectus abdominis* could be made to contract alone, it would clearly approximate the sternum to the symphysis pubis and flex the lumbar spine. The part of the body actually moved would depend on which was the fixed point: either the pelvis would be tipped backwards or else the thorax bent forwards. When standing upright the thorax is the least fixed and must therefore be the part to move. If it were desired to fix the thorax and move the pelvis, the only muscles that could do so would be the *erector spinae*; but consider what must happen if the *rectus* and the *erector spinae* contract together. These muscles are bridging the gap between two bony boxes which are joined by a curved flexible rod. Their simultaneous contraction can have only one effect, to move the thorax bodily nearer to the pelvis and increase the lumbar curve (Fig. 6). The *rectus abdominis* can therefore have little effect on the inclination of the pelvis when standing erect. Its action (in addition to that of retaining the abdominal contents) is to flex the lumbar spine.

The *erector spinae* control extension of the spine. The range of movement is largest in the lumbar region where there is a large and powerful mass of muscle to raise the trunk from the flexed position. In the dorsal region the range of movement is very much smaller; the *erector spinae* is much less powerful but there are other muscles which assist it. The

dorsal curve is flattened appreciably with every inspiration, and for this the muscles of respiration—the diaphragm, intercostals, &c.—are largely responsible. These muscles must therefore coöperate

FIG. 6.—Simultaneous contraction of the *rectus abdominis* and the *erector spinae* must increase the pelvic inclination.

in maintaining normal posture, and also in recovering from a slack position in which there is a slight increase in the dorsal curve to a good posture.

The weakest part of the extensor mechanism of the spine is in the upper lumbar and lower dorsal regions. The mass of the *erector spinae* is getting smaller and the change of curve from concave to convex is taking place, making it mechanically a vulnerable spot. Loss of tone in the extensors will allow the whole weight of the upper part of the body to come on to the spine and produce one of the commonest deformities, a dorsolumbar kyphosis (Fig. 10). In the early stages the deformity can be straightened by the action of the *erector spinae*. Later on however it seems that the ligaments become contracted and sometimes the vertebrae become wedge-shaped so that active correction is no longer possible.

To summarise—the inclination of the pelvis is controlled almost entirely by the muscles surrounding the hip joints. The abdominal and spinal muscles have little direct effect on the pelvis; their action is to keep the body upright whatever the pelvic inclination by varying the curves of the spine.

TYPES OF DEFORMITY

It is essential for the maintenance of the upright position whatever abnormality of posture may be present that the centre of gravity of the whole body should fall somewhere within the area occupied by the feet. This limits considerably the possibilities of postural variation and analysis shows that only two components contribute to make up the majority of cases. Firstly there is nearly always an alteration in the pelvic inclination which may be increased or decreased. Secondly there may in addition be a dorsolumbar kyphosis. These two variables combine to produce four distinct groups which are adequate to classify the majority of cases. (In the following, normal spine means one which has no

FIG. 7.—Types of postural deformity

intrinsic error and whose curves become normal when the pelvic inclination is corrected)

Forward tilt of pelvis plus	{ normal spine dorsolumbar kyphosis
Backward tilt of pelvis plus	{ normal spine dorsolumbar kyphosis

lumbar lordosis
sway back
flat back
round back

In the ensuing account of the types of postural deformity the pelvis is taken as the starting point for description, not because it is necessarily the causal factor, but because it is the base on which the column of the spine is supported. The problem then becomes largely the mechanical one of explaining how the centre of gravity is adjusted (Fig 7). A theoretical explanation of the production of the deformities is given for the sake of convenience, but it is not suggested that it is the actual manner in which they arise during life. The process is one of gradual "slumping," rather than of separated movements.

LUMBAR LORDOSIS

The mechanism of the production of lordosis can be visualised as follows. First the pelvis is allowed to tilt forwards, and with it the whole trunk. Then the centre of gravity is restored by bending backwards in the lumbar region and increasing the concavity (Figs 7*b* and 8). The mastoid line bears much the same relation to the large joints in the corrected and uncorrected positions. The spine is pretty well balanced so the erector spinae have little work to do and can share in a general slump of the anti-gravity muscles, thus permitting a slight increase in the dorsal curve.

The condition is often referred to as kypho lordosis, but the increase in the dorsal curve is slight and unimportant. The dorsolumbar curves in the corrected and uncorrected positions were recorded in a number of cases with malleable metal strips. The strips were then outlined on papers which could be superimposed to show the amount of change.

The change is surprisingly small in the dorsal region, and the kyphotic appearance of the dorsal spine in such cases is partly due to the exaggerated curves above and below. Tracings of photographic reductions are shown in Fig 9.

Internally rotated legs and valgus feet are very commonly present in cases of lordosis, as in all other deformities in which there is an

increased pelvic inclination. The feet can only be corrected after the general posture and the rotation of the femora has been altered (Wiles 1934).

The pelvic inclination has been measured in 24 female patients undergoing treatment for lordosis. The

average angle was 39° , with a range of 34° to 41° (average for normal women 28°).

The clinical picture in a typical case is one of a forward tilted pelvis, increased lumbar and dorsal curves, shoulders drooping and head poked forwards; internally rotated legs and valgus feet. The dominating feature, however, is the pelvis, the rest of the deformities are secondary to it. This has often been demonstrated when examining untreated cases. The patient has been shown how to use the glutei to restore the pelvic inclination to normal and the posture of the trunk has at once returned almost to normal.

Treatment, so far as it is local at all, should be directed chiefly to the glutei. To concentrate on the abdominals, as some workers tend to, can achieve little by itself because these muscles play only a secondary part in this deformity.

SWAY BACK

This name originated in America for a postural type which seems to be very common there. Analysis along the lines already indicated shows it to consist of a forward tilted pelvis in association with a dorsolumbar kyphosis. The degree of kyphosis is often quite small, really no more than a flattening of the upper part of the lumbar concavity. However, even this amount is sufficient to prevent the spine compensating to the tilted pelvis by a general increase in the curve of the lumbar region, as occurs in the previous type. Instead the centre of gravity is restored to a stable position by bending the spine sharply backwards in the lower lumbar region (Figs 7*d* and 10). In this position,

FIG 9.—Showing the small change in the curve of the dorsal spine in two cases of lumbar lordosis (see text).

FIG 8.—Left lordosis. Right corrected by decreasing the pelvic inclination.

FIG 10.—Left sway back. Right decreasing the pelvic inclination improves the posture but cannot remove the dorsolumbar kyphosis.

FIG 11.—Left, round back, Type 1. Right: the pelvic inclination is increased but the back is still abnormal.

the legs are inclined slightly forwards at the ankles so that the pelvis projects forwards. The mastoid line passes well behind the great trochanters and a plumb line from the most prominent part of the dorsal convexity falls behind the sacrum. Internally rotated legs and valgus feet are commonly present, and not infrequently there is a total scoliosis as well.

In the cases examined, the average inclination of the pelvis was 37° the range being 35–41°.

The dorso-lumbar region of the spine is only occasionally sufficiently mobile to allow active correction by the erector spinae. As a rule there is such limitation of movement that the deformity is not even corrected when a wedge is placed under the upper lumbar spine and the patient lies limply across it. The limitation of movement is sometimes due to structural changes in the vertebrae which can then be shown by X rays to be wedge shaped.

From the point of view of treatment away back differs from simple lordosis in that correction of the pelvic angle does not enable the spinal curves to be restored to normal. Treatment has therefore to be directed at first to increasing the mobility of the spine—one of the most difficult problems of postural correction.

FLAT BACK

Flat back is just as much a postural deformity as any of the other conditions discussed. The pelvis is abnormally flat and the spine is flattened in compensation. Such cases however are seldom if ever sent to orthopaedic departments on account of their posture and adolescent patients are rarely seen in remedial clinics undergoing treatment for flat back. People with flat back come under orthopaedic observation later in life complaining of back ache, sacro-lumbar strain or other troubles of a mechanical nature. By this time the spine is too stiff for any change of posture to be possible and only symptomatic treatment can be given. A great many of these complaints could be prevented if only parents and school medical officers could be brought to realise that a lovely straight back is not necessarily ideal and could be persuaded to send such cases for treatment during childhood.

ROUND BACK

This name has been adopted for a rather less clearly defined group of cases in which a decreased pelvic inclination is associated with a dorsolumbar

kyphosis. The centre of gravity is stabilised by mechanisms of two different types. In type 1 which gives the name to the group the trunk is bent forwards in the lower lumbar region obliterating what is left of the lumbar curve. The legs are inclined slightly backwards at the ankles so that the pelvis is displaced relatively backwards and the great trochanter is behind the mastoid line (Figs 7e and 11).

The mechanism in type 2 is very similar to that in sway back. The legs are inclined forwards and the trunk backwards causing a lower lumbar angulation, the great trochanter is in front of the mastoid line (Figs 7f and 12).

The treatment of this group presents just the same problems as sway back—the difficulty of restoring the upper part of the lumbar concavity.

DORSAL KYPHOSIS

There is a group of cases of kyphosis affecting principally the dorsal spine that was at one time regarded as being postural in origin. Recently however such cases have been shown to be associated almost invariably with disease of the intervertebral disks and the epiphyses of the bodies of the vertebrae. These cases therefore do not fall under the heading of postural deformities.

Treatment

Before embarking on the treatment of postural deformity inquiry should always be made into its cause. In cases in which there is no mechanical cause the factors discussed under aetiology have to be considered. Especially is the question of under-nutrition worth attention to give remedial exercises to an undernourished patient is only adding to his troubles. When no other cause is forthcoming investigation should be made into possible psychological factors. This involves inquiry into the psychological make up of the patient and his home conditions. In any case of doubt or when the problem of emotional readjustment is beyond a resolution it is advisable to obtain the assistance of a medical psychologist. It is of little use to expect a patient to co-operate in remedial work when he is

FIG 12.—Left, round back, Type 2. Right: increasing the pelvic inclination improves the posture but cannot remove the dorsolumbar kyphosis.

trying to grapple with an emotional problem which is, to him, of much greater importance

The treatment of postural deformities falls into three stages. Firstly, restoring sufficient mobility to enable correction to be made, secondly, acquiring voluntary control over the movements that produce correction, and thirdly, the establishment of new reflexes that will maintain permanently the correct posture. Any good system of remedial work deals with all three stages simultaneously, they are only separated here for discussion.

Mobility is limited to an extent sufficient to prevent correction of the deformity in only a proportion of cases. This is of importance particularly in the dorsolumbar kyphosis of sway back, and the limitation of extension of the hips in some cases in which the pelvic inclination is increased. There are three causes of the loss of mobility, one or more of which may be present in any case.

- (1) Structural changes in the shape of the bone,
- (2) Contracted ligaments, and
- (3) Shortened muscles

A *structural change* in the shape of the bones occurs in some cases of dorsolumbar kyphosis. It is impossible to restore the shape of the bones by any remedial measures. Indeed it is doubtful if any of the most drastic corrective machinery used by orthopaedic surgeons has any effect on it. The object of remedial work in structural cases is to develop such compensatory curves as will give the greatest mechanical and æsthetic advantage.

Contracted ligaments and joint capsules may be found preventing correction of dorsolumbar kyphosis or limiting extension of the hips in cases with increased pelvic inclination. The stretching of contracted ligaments, as of any other fibrous tissue, is a matter of difficulty. Forced passive movements, either with or without an anæsthetic, result in tearing the ligaments and do more harm than good. The most effective method of stretching them at all rapidly is prolonged traction. Head suspension is therefore very valuable when dealing with contractions affecting the spine and, if carefully supervised, is well tolerated by patients. Active movements carried to their extreme range and repeated frequently may be of some assistance in stretching ligaments, but care must be taken to see that the movements are not too violent and to ensure that they are localised to the affected region.

"*Shortened muscles*" probably play a part in hindering correction of most deformities that are at all severe. The process of increasing the length of muscles is often referred to as muscle stretching. This is hardly the right word to use because, so far as is known, muscle fibres cannot be stretched—they have to be made to relax more fully. This is not merely an academic point, but a practical one which directly affects treatment. The normal physiological response of a muscle to stretching is contraction, and the harder it is stretched the more strongly it contracts. Therefore, passively stretching a muscle calls into action this "stretch reflex" and makes the muscle contract more. The passive stretching of muscles with the idea of lengthening them is a procedure that should be abandoned, it can do no good, and, if carried to an extreme, it will do harm.

The lengthening of a muscle can be achieved by getting it to relax more fully. A muscle relaxes reflexly when its antagonist contracts, but, when a "free" movement is made—that is, one without any resistance to it—the muscle does not relax completely, it maintains enough tone throughout

the movement in order to keep the joint under control, and it will go on contracting even when the extreme of movement is reached. However, when a movement is made against resistance, the muscle is enabled to relax more fully because control of the joint is obtained by means of the pressure between the resistance and the contracting muscle. Hence, to stretch a muscle, its antagonist must be made to contract against resistance and continue to work against the resistance when the extreme of movement has been reached. Thus, if the flexors of

the hip are contracted, the appropriate exercise is to extend one leg backwards against gravity whilst keeping the trunk vertical, in the manner of the "battement derrière" of the Classical Ballet (Fig 13). Backward bending from the hips is useless because the movement is made by gravity with the flexors contracting strongly to control it.

Voluntary control over the movements that correct a postural deformity is easily taught when adequate mobility is present. In those cases in which mobility is limited at the commencement of treatment, control is learnt automatically whilst mobility is acquired.

In cases where the pelvic inclination is increased, the glutei are the correct muscles to restore it to normal. The glutei are the principal extensors of the hips, and tilting backwards the pelvis is exactly the same movement as extending the hips. Patients should not be told to "draw the stomach in" or they will use the abdominals. They should be given some such order as to "tuck their tails under them," and then be watched to see that they really are using the glutei. Some patients tend to use the hamstrings for tilting the pelvis, this can be prevented by making the movement in the kneeling position so as to reduce the power of the hamstrings.

The establishment of *new postural reflexes* is the final aim of all remedial treatment. It is just here that so many systems, including that officially recognised in this country, show their greatest weakness. They are mainly concerned with strengthening muscles and increasing mobility, and make but little effort to teach the patient how to hold the new posture. Remedial work requires "postural fixation" not "postural change," so, when it is possible to make a voluntary correction, exercises that move the parts of the body principally concerned can do no good. Exercises must be directed towards keeping the

FIG 13 — The correct movement to encourage extension of the hip and spine

parts as still as possible whilst the rest of the body is moved. Thus the patient is taught to keep a good posture during every variety of movement.

It would be out of place to attempt to describe here any particular remedial system that will fill the criteria set out. It requires but little ingenuity to invent one once the principles are understood. I am concerned mainly to emphasise that it is not movement, but absence of movement of any given part that is essential for the establishment of a postural reflex. Success or failure of treatment depends on the extent to which the co-operation of the patient is obtained. During the remedial class it is only possible to teach the patient how to get into the new posture and how to hold it under a variety of conditions. The establishment of an unconscious reflex that will hold the new posture permanently is only possible if the patient continues to try after the class is over and it can never be done if as soon as he is out of the room he just drops back into the old posture. For treatment to be successful the patient really must want to be cured and make up his mind to succeed. The personality of the teacher and his ability to win the patient's confidence and keep his interest is of just as great importance as a knowledge of remedial technique.

Summary

1 The regulation of posture is a function of the central nervous system which determines the length at which the muscles are habitually held. The strength of the muscles is of less importance.

2 The importance of rapid growth, undernutrition and psychological factors in the aetiology of postural deformities is emphasised.

3 A new instrument is described for measuring the pelvic inclination. This angle in normal adult males averages 31° and in females 28°. In children it is somewhat less but it increases up to 11 years of age when the adult level is reached.

4 The pelvic inclination is regulated by the muscles surrounding the hip joint and not by the trunk muscles.

5 Deformities are classified on the basis of their two principal components—variation in pelvic inclination and the presence or absence of a dorsolumbar kyphosis—into four types: (1) lumbar lordosis (2) sway back; (3) flat back; (4) round back.

6 Final correction of a deformity can only be made by establishing new postural reflexes. This can never be done by movement but only by absence of movement; therefore exercises must be designed to keep still the parts of the body concerned.

It is a pleasure to thank Prof. Samson Wright for permission to work in the department of physiology at the Middlesex Hospital medical school, and also the honorary staff of the Royal National Orthopaedic Hospital for allowing me to examine a number of their patients. I also wish to express my indebtedness to Sir Frederick Menzies and the London County Council for permission to attend the medical examinations of elementary school children and to Mr Paul S. Newby, director of physical training at the Central YMCA, and Miss E. M. Prosser, sister-in-charge of the massage department of the Middlesex Hospital for their kindness in procuring me normal subjects for measurements of pelvic inclination and to the many subjects themselves, whose great patience has made this work possible.

PRURITUS ANI*

By JOHN W. RIDDOCH, M.C., M.B.

F.R.C.S. Edin.

HOY SURGEON TO THE MIDLAND HOSPITAL, BIRMINGHAM

THE sensation of itching like pain is a protective function of the body. Pain causes various reflex acts while itching leads to scratching or rubbing to remove such things as insects which have a harmful effect on the organism. Pain is transmitted by the autonomic as well as the cerebro-spinal nervous system but itching is carried by the somatic nerves alone as only these supply the parts where itching is biologically useful. If however scratching is unlikely to do good itching must be regarded as pathological and worthy of the name pruritus. It is apt to occur more frequently about the various body orifices than elsewhere; no doubt to get rid of excess discharge and at two of these the anus and the vulva it not infrequently becomes pathological and so severe as to acquire the status of a syndrome or even an actual disease.

Anal irritation of minor degree occurs in a considerable proportion of cases of internal haemorrhoids and other local abnormalities but the term pruritus ani denotes a condition where irritation is relatively severe. In it the symptoms are often worse at night soon after retirement to bed and they may seriously interfere with sleep. Sometimes there are intermissions when the irritation is in comparative abeyance and the patient may think he has got over the worst of his trouble only to be sadly disillusioned by the next attack. Carlyle could not have known of this disease when he said that the greatest pleasure in life is to scratch the part that itches for the patient gets little relief from his efforts. The sensation is described in such terms as smarting, tickling, burning, pricking and it is situated in the lower end of the anal canal, the anal verge and a variable extent of the perianal region. The affected skin may be surprisingly normal in appearance but it is usually thickened and somewhat sodden—a change described as lichenification—and often shows superficial cracks radiating from the anus. Superimposed on this scratching and formidable remedies may have grafted a traumatic dermatitis and though septic infection is thus introduced it is curious to note that inguinal adenitis rarely if ever occurs (O'Donovan 1930).

Aetiology

There must be few diseases that have been ascribed to so many causes as pruritus ani. Lord Horder (1935) has said it is the merest tyro who supposes that local pruritus (is due) to local causes. I am quite sure that pruritus ani may be of entirely general origin. On the other hand Lockhart Mummery (1915, 1934) has long believed that a local cause is present in all cases but that in some our knowledge is insufficient to recognise it. It is agreed that anal pruritus may be caused by local

conditions that give rise to a discharge, such as fissure, fistula and infected anal crypts, and proctitis, colitis, and ulcerative diseases of the bowel. It is likely that threadworms produce itching in this way. Internal hæmorrhoids and polypi may induce a seepage of mucus by excess of secretion or by allowing it to escape by prolapsing into the sphincters and preventing their closure. Scarborough (1933) believes that all cases arise in such a manner and can be cured by removal of the cause but his claim is unique.

There is no doubt in the minds of a colleague and myself that mucus can cause anal irritation as we have produced it on ourselves by its application, but it is probable that some sensitivity must be present as well, for it is not uncommon in some rectal conditions to see the perianal skin moist with mucus or other discharge without causing symptoms. Dirt, excessive local sweating, and pediculi may cause irritation but can easily be recognised. Bacterial and fungus infections have been put forward as causes but have not found acceptance. Where a careful search has failed to reveal any local abnormality distant lesions have been blamed, especially gynaecological abnormalities, conditions of urinary obstruction such as stricture, prostatism, and stone in the bladder, and cholecystitis and diseases of the liver. In the absence of these, focal sepsis, gout, rheumatism, and diabetes are commonly mentioned, though with what justification I am unable to say. The fact that attacks may be brought on by tea, coffee, and alcohol, and in some people by cheese, fish, strawberries, &c., has added allergy to the list of causes, and lastly, and perhaps inevitably, the disease is often regarded as a neurosis.

In order to escape from this diagnostic maze some classification is necessary and I propose to distinguish between those cases due to a discharge and those which are not. I regard cases associated with a discharge, and cured by its removal, as cases of exogenous dermatitis. In them the rash and irritation tend to pass backward in the natal cleft and forward on to the scrotum owing to the spread of the offending secretion in the directions of least resistance, and though in some of these cases the irritation may be severe, in the majority it is comparatively mild. True or idiopathic pruritus ani is however a separate disease, it may occur in a severe form with little, if any, alteration in the naked eye appearance of the skin, when it is coincident with an exogenous dermatitis it persists after the latter has been cured, it has a pathology of its own which is not, as is commonly supposed, the result of scratching, it may have superimposed on it a traumatic dermatitis due to scratching or irritant applications, but when this has cleared up after suitable treatment the pruritus remains, and it occurs in the complete absence of abnormalities in the anorectal region as judged by recognised standards and also in the absence of any general disturbance of health.

The sensation of irritation arises in the epidermis for, as pointed out by O'Donovan (1936), irritation ceases if ulceration occurs. It is due to minor but more or less rapid changes in tension (Bunch 1912), such as are caused by the burrowing of the *Icarus scabiei* or when tight garments are suddenly discarded. It is a feature of whealing and Sir Thomas Lewis (1927) mentioned itching when a wheal was caused by freezing the skin and no irritant was introduced from outside. It occurs in many skin diseases and in the oedema of the epidermis is commonly found, and it is reasonable to assume that

where the circulatory balance is upset, as it is in oedema, abnormal variations in tension are apt to occur and irritation is likely to arise.

In this paper I hope to show that idiopathic pruritus ani is caused by oedema of the perianal skin following on stasis in the external hæmorrhoidal veins, in other words, it is due to external piles.

Histology

As regards the microscopic appearances of pruritus ani Crawford (Haskell and Smith 1936) regarded them as essentially those of a low grade inflammatory process with proliferative changes. He found much thickening of the epidermis, dilatation of the superficial blood vessels and lymphatics, extensive infiltration of white cells, usually small lymphocytes, and fibrosis in the deeper layers of the cutis with oedema superficially. Montgomery (Rankin, Bagen, and Bue 1932), reporting on 5 cases, gave similar findings but believed that the changes resembled those of neurodermatitis and urticaria rather than inflammation. Further, it is important to note that in comparing cases of normal naked eye appearance with those where frank change was present he found the microscopic appearances differed in degree only and not in kind.

With the help of Dr Whitelaw and Dr Felix Smith I have examined sections from 6 cases, 5 of these presented various degrees of hyperkeratosis, but one showed no such alteration. In all there were changes similar to those described by Crawford and Montgomery. The epidermis was thickened, in some parts to twice its normal depth, and showed various degrees of acanthosis. Oedema was evidenced by swelling of the prickle cells and poor staining of their nuclei, and by the fact that the intercellular channels were more evident than in normal skin. Some thickening of the horny layer was usually present and in one case this was very marked. In the cutis there was dilatation of the blood vessels, especially the veins, and obvious oedema shown by separation of the connective tissue fibres and poor nuclear affinity for stain. The lymphatic vessels were also dilated. There was usually some lymphocytic infiltration of the papillae and the subpapillary layer, most marked round the vessels, but this feature was very variable, being absent in some parts of the sections (see Figure). An occasional eosinophil was seen in one section only.

It might be said that the lymphocytic infiltration suggests the presence of an irritant factor, but it is not a very pronounced feature except in one case and is hardly noticeable in some areas of the sections. Also in three normal specimens of perianal skin examined a certain number of lymphocytes were seen. Their presence in any number is not a characteristic of the disease and the essential change is one of oedema. Such oedema, as elsewhere in the body, can be produced by local venous stasis. It is, I think reasonable to assume that in the earliest stage of the pathological change pruritus has not manifested itself but the threshold to irritation is lowered, the skin is in a prepruritic state.

Effect of Venous Stasis

Let us now see how the theory of venous stasis agrees with the clinical manifestations and the therapeutics of the disease. A dramatic feature in the symptomatology is the fact that a patient who is free of symptoms during the day may be attacked by intolerable itching soon after getting into bed. He gets up and applies his favourite powder or ointment and relief sooner or later follows.

He goes to bed again and again the itching starts. He may find that the only way he can obtain sleep is to spend the rest of the night in a chair. The usual explanation that all itching is worse at night because one is warmer in bed and the mind is not occupied is hardly adequate. In the erect position the pressure of the valveless portal system is conveyed to the anal veins and when the patient lies down this pressure ceases and there is a sudden drop in tension in the peri-anal veins which is transmitted to the skin of the area. This would account for the great exacerbation that occurs at night and the same train of events is seen in varicose eczema of the legs.

Neurosis is merely of interest because the neurotic complains more bitterly of his symptoms than the normal person and if he has no disense to show to the uninitiated the poor fellow gets little sympathy.

Clinical Findings

The skin in the lower end of the anal canal and its vicinity is normally very thin and thrown into folds only a millimetre or two in width. In cases of pruritus ani the folds are much wider and the skin is felt to be thicker than normal when picked up between the finger and thumb owing to oedema even when no other change is present. When an

A. Normal perianal skin, note density of staining. ($\times 80$).

B. Pruritus ani, showing pallor of dermis and epidermis due to oedema. ($\times 80$).

C. Severe pruritus ani. The papillae are flattened out and there is a polypoid formation with great increase in thickness of the keratin layer and epidermis. ($\times 20$).

As regards the part played by gynaecological conditions inflammatory affections will cause general congestion of the pelvis and pelvic tumours may interfere with the venous return in both the superior haemorrhoidal and internal iliac veins and so cause anal congestion and stasis. A similar result will be brought about by the increased intra abdominal tension involved in the straining of urinary obstruction and affections of the liver by congestion or by mechanical means will react unfavourably on all the radicles of the portal system including the anal veins.

The effect of certain foods in sensitised individuals is explained by the fact that the ingestion of any substance that acts on the skin vessels will lead to changes of tension in that structure and though these changes may not be sufficient to cause any sensation in normal areas they may produce itching in a pruritic zone such as has been adumbrated. Allergy is thus accounted for. Slight rises in temperature produced by focal sepsis would act in a similar manner and the effect of alcohol is also explained in this way. The conception of a pruritic state also helps us with regard to the action of tea and coffee in starting attacks as caffeine facilitates the reception of sensory impulses (Cushny 1924).

I will not attempt to explain the supposed importance of gout rheumatism and diabetes; as previously stated they are often mentioned, but their relationship to pruritus ani is open to doubt and Lockhart Mummery (1915) has said he has never seen a bad case due to diabetes.

anoscope is inserted and slowly withdrawn past the mucocutaneous junction the skin below this line forms large bulges through which the bluish colour of the enlarged underlying veins is often apparent.

Treatment

Turning now to the effects of treatment Morley (1916) noted that pruritus ani sometimes cleared up after the injection treatment of quite small and symptomless internal piles. I have confirmed this on many occasions and would go further and say that benefit may be obtained by similar injections in the complete absence of any sign of internal haemorrhoids. This treatment acts by destroying the veins of the internal haemorrhoidal plexus and relieving back pressure on the external haemorrhoidal veins. It is not surprising however that the results of such treatment vary as the anastomosis between the two plexuses is not constant and the external plexus has connexions with the systemic veins.

Most operations are based on that of Sir Charles Ball (1905) which was devised to cut all the sensory nerves to the affected part. An essential part of the procedure is to undermine the skin of the anal canal to above the mucocutaneous line. Lockhart Mummery (1934) speaks well of this operation and states that though sensation returns in 4-6 weeks the pruritus is cured in most cases. It is stated that the skin operated on must be rendered completely anaesthetic. In six recent cases I have made a curved incision on each side of the anus and undercut the skin of the anal canal to just above the mucocutaneous line.

taking special care to destroy the veins, extensive undermining was avoided as far as possible and sensation was not completely lost. In five cases the pruritus disappeared and the skin became normal in appearance in a short time. In one case the pruritus reappeared after only 14 days, but it yielded to subcutaneous sclerosing injections and I regard this failure as due to faulty technique. From these results it would appear that complete section of the nerves is not necessary for cure, as far as one can judge at this stage, and here I would point out that it is impossible to carry out Ball's operation without destroying many if not all of the underlying veins.

Sir Frederick Wallis (1911) believed pruritus ani was due to some lesion at the mucocutaneous junction and he excised this along with the skin of the lower part of the anal canal. He claimed good results from this operation but again it is impossible to carry out the procedure without excising the neighbouring veins.

The subcutaneous injection of alcohol, dilute hydrochloric acid, and other substances was introduced as a substitute for operation to destroy nerves but the beneficial effects claimed can be explained in a similar manner. Solutions of anaesthetics in oil will stop the itching temporarily and allow a scratch dermatitis to subside, but they also will tend to strangle the veins by causing fibrosis.

As far as external applications are concerned they may be very important in the treatment of patients who have become sensitised to some superadded infective skin condition, and in these cases the co-operation of a skin specialist is often necessary, but in the treatment of the true idiopathic form the value of such remedies is belied by the very numbers that have been recommended. Radioactive mud, colon lavage, vaccines, ionisation, artificial and natural sunlight, &c., may, I think, be placed in the same category and their lack of value in treatment is easily understood in the light of the theory presented.

The claims put forward on behalf of Röntgen rays are usually moderate, but they appear to have some curative value and the explanation of this may be a destructive effect on the blood-vessels.

Conclusion

In conclusion, I believe that the severest form of pruritus ani and the occasional itching found in association with internal piles are merely different degrees of the same condition and that the underlying cause is oedema of the skin due to venous stasis. If I have not convinced you I can at least say that I have found this view to be a useful working hypothesis.

I wish to express my indebtedness to Dr W Whitelaw for his interest in the pathological side of the work and for preparing the photomicrographs.

COMPARATIVE STUDY OF TUBERCULIN REACTIONS AND RADIOLOGICAL FINDINGS

By O SCHEEL, M.D.

PHYSICIAN TO ULLEVAAL HOSPITAL OSLO NORWAY

THERE is still no agreement as to where we are to fix the limit dividing positive from negative tuberculin reactions and as to which technique should be used, in particular whether Pirquet or Mantoux. During recent years in Norway we have regarded the Pirquet reaction, by the scarification method, as positive when induration measures 2 mm. or more after 48-72 hours, the Mantoux reaction is considered positive when induration measures 10 mm. or more after 48-72 hours. In France also the Pirquet technique is employed as a rule. In Sweden, Denmark, and England, on the whole, the Mantoux test is preferred and most workers fix the limit between positive and negative reactions lower than we do. Thus D'Arcy Hart fixes the minimum for a positive Mantoux reaction, after 48-72 hours, at "an area of erythema or erythematous infiltration" whose greatest diameter is 5 mm., he uses up to 10 mg., and on occasion 100 mg., of tuberculin. Arborelius considers a second Mantoux test with 1 mg. tuberculin as positive when there appears after 48 hours a definitely palpable induration and an area of erythema measuring at least 5 mm. by 5 mm. Thus both these observers fix the minimum for positive reaction lower than we do and think our method too insensitive, with the result that we obtain too few positive reactions among healthy subjects—viz., approximately 50 per cent at twenty years of age, while Arborelius obtains 85 per cent and D'Arcy Hart, from twenty one years of age, 95 per cent.

Now it is generally agreed that on the whole we can distinguish between pronounced tuberculin positive individuals and completely tuberculin negative individuals, which corresponds to infected and uninfected individuals. But the dividing line between these two groups is difficult to determine, for two reasons: on the one hand there are the false reactions which are due to non specific substances in the tuberculin, especially when more than 1 mg. of tuberculin is injected, on the other hand, the reaction may fail because of insufficient dose, faulty technique, or for other reasons. I have disregarded in the following the anergy which is seen, for example, in certain diseases and among the aged, for it has no interest in connexion with this material which consist of young healthy subjects.

In order to fix the limit between positive and negative reactions all observers argue from certain characters of the definite positive and definite negative reactions—viz., the size of the reaction, its mode of development in the course of the first few days, and the result of repeated tests with the same or increasing doses. But in this way evidence is sought in that which is to be proved, this is the case, for example, if we regard the Mantoux test as the reliable one and compare the various Pirquet responses with that of the Mantoux test. This mode of reasoning involves a logical *circulus vitiosus* in which that which is to be proved is used as argument in the chain of reasoning: both argument and conclusion are links in the same chain, the tuberculin reaction itself.

In order to break this vicious circle it is therefore necessary to control the tuberculin reactions by facts obtained from an independent source of evidence.

I may first reiterate the fact that with our Pirquet technique we always find a higher tuberculous morbidity among the Pirquet-negative than among the Pirquet-positive when both groups are exposed to infection. This corresponds to the known experimental finding that an initial infection with tubercle bacilli in animals has a more serious outcome than a later superinfection with small doses of tubercle bacilli. With our Pirquet technique therefore we distinguish on the whole two different immunological groups but this control is not sufficient to draw any exact line between infected and uninfected

THE INQUIRY

In an attempt to determine with more certainty this limit between positive and negative I have compared the tuberculin reactions with the simultaneously obtained radiological findings in 1097 students. The great majority of the material is derived from the university tuberculous clinic at Oslo where the radiological diagnosis is made by the radiological department of the State Hospital; all the students are radiographed. The tuberculin tests have been carried out and interpreted by various doctors from my department at Ullevaal Hospital but the same procedure is always followed. All those examined were healthy without previous history of tuberculous disease and not vaccinated with BCG.

851 STUDENTS REGARDED AS TUBERCULIN NEGATIVE

	Total	Pirquet changes	Lung shadows	Calcified foci in lung or hilus
Pirquet 0 mm				
Mantoux 0 mm	585	43	12	0
Doubtful Pirquet or Mantoux	139	43	0	0
Two Pirquet tests, 0 mm	65	31	0	0
Single Pirquet test, 0-1 mm	61	0	10	32
1st Pirquet neg.				
2nd test Mantoux 1-0 mm	63	48	0	0

846 STUDENTS REGARDED AS TUBERCULIN POSITIVE

1st Pirquet, 0 mm				
2nd test Mantoux ≥ 10 mm (or Pirquet positive)	81	62	25	0
Pirquet 2 mm	40	0	0	0
3 mm	61	33	25	131
4 mm	94	0	41	132
5 mm or more	556	42	50	162
1st Pirquet neg.				
2nd test Mantoux 10-40 mm	89	34	1	1

neg. = reaction.

We see from the accompanying Table that the 851 students whom we have regarded as tuberculin negative fall into four groups:

- (1) First tuberculin test by Pirquet method and second test by Mantoux method give no measurable induration after 48 hours.
- (2) Doubtful reactions: first test (Pirquet) may be doubtful or feebly positive 1-5 mm induration; later Mantoux test negative or the later Mantoux test may give 1-0 mm induration (in some cases 10 mm or more but a further reaction is then negative).
- (3) Two successive Pirquet reactions negative.
- (4) A single Pirquet test with 0-1 mm induration as result.

In 846 students whom we have regarded as tuberculin positive there is first a group in whom the first test (Pirquet) is negative, the second test (Mantoux or in a few cases Pirquet) is positive. In the remaining groups only a single Pirquet test has been made and the reactions have been 2-3

4-5 mm or more (induration). In some cases giving a Pirquet of 2 mm, a Mantoux test has been carried out.

In the two groups tuberculin negative and tuberculin positive, I have also indicated by asterisks the results of a second test (Mantoux): the induration measuring 1-0 mm in the negative group 10-40 mm in the positive group. Among these last, 89 in number 62 gave induration measuring only 10-20 mm. The Mantoux tests are always carried out with tuberculin dilutions supplied in sealed ampoules (1/10 c.c.m. = 1 mg.) these are opened after the lapse of some days or weeks on occasion some months. A freshly prepared dilution of tuberculin gives as a rule a slightly more powerful reaction but, according to comparative tests we have recently made the difference is not great.

I have now grouped these tuberculin positive and tuberculin negative individuals according to the radiological findings. Three groups have been considered:

(1) Changes in the pleura usually diaphragmatic adhesions, sometimes thickening over the apex, but without changes in lung or hilus.

(2) Shadows in the lung fields, in some cases with changes in the pleura, but without calcification.

(3) Deposits of calcium in lung tissue or glands, in these there may be in addition pleural and lung shadows.

These radiological changes are distributed in the following way among those we have regarded as tuberculin negative and tuberculin positive respectively:—

The purely pleural changes appear with approximately equal frequency among tuberculin negatives and positives 0-05 per cent. The purely pleural changes are therefore clearly not of tuberculous aetiology but must be due to non-specific affections such as for example bronchopneumonia. The distribution of pleural changes which are combined with lung or hilus changes is not revealed in the Table.

The pure lung shadows without calcification presumably corresponding to a deposition of fibrous tissue are distinctly more frequent among the positive (0-09 per cent.) than among the negative (0-10 per cent.); they may obviously be due to non-specific lung infiltrations but are more frequently a sign of a healed tuberculous process.

Calcified foci occur though rarely among the definite tuberculin negative (0.7 per cent.) which is not surprising; there are other causes of calcification besides tuberculous—e.g. calcified lung emboli intra alveolar ossification; in pneumonia also there may occur necrosis of lung tissue leading to abscess formation and presumably also in glands; and where there is necrosis the conditions necessary for calcification are always present. In the group who received only a single Pirquet test with negative result there appear also two cases showing calcification; but here the numbers are so small that we must not lay much stress upon the percentage—3.2. We do not know either what result would have been obtained by a repeated Pirquet test on these subjects.

In the group which we have regarded as tuberculin positive we find calcified foci with much greater frequency but only when the Pirquet test has given an induration measuring 3 mm or more. The frequency of calcified foci in these groups varies from 12.2 to 16.2 per cent. These figures represent only a fraction of the calcified foci actually present; thus Friemann Dahl and Wæster by radiography of 200 excised lungs from autopsy material extending

over all ages, found calcification shadows in 71 per cent. Even though the frequency of calcified foci in our material is thus much less, we nevertheless find calcified foci in the positive groups approximately twenty times as frequently as among the purest negative group. This frequent calcification is therefore obviously an index of tuberculous infection, and this infection is revealed by a Pirquet reaction of 3 mm or more.

On the other hand, we have no calcification shadows in two of the groups of our material which we have regarded as tuberculin positive—namely, (1) those in whom the first Pirquet reaction is negative while the second test, Mantoux or Pirquet, is positive, and (2) those in whom the first Pirquet test gives a reaction measuring 2 mm. This finding strongly indicates that at any rate the great majority of these feeble tuberculin reactions do not correspond to tuberculous infection.

If we consider in particular those cases (indicated by asterisks in the Table) where the second test—a Mantoux test—has given a more or less pronounced reaction after a negative response to the first Pirquet test, we find only a single case with calcification. According to this it appears doubtful whether the Mantoux test performed after a negative or doubtful Pirquet test has any significance or is at all necessary. We must, however, qualify this conclusion in two ways. Firstly, a second tuberculin test can probably reveal a tuberculous infection if the reaction be sufficiently powerful, even though the first test was negative. In most of our cases the second reaction was of moderate extent, and we can therefore neither confirm nor deny the possibility of a "sensitisation" effect, but must regard it as possible. Secondly, we do not regard our figures as of universal application, it would seem that other Norwegian observers have found calcification in association with doubtful or negative tuberculin reactions more frequently than we have, and we are unable to decide whether this divergence is due to any difference in interpretation of tuberculin reactions or radiological appearances. Our radiological control applies therefore chiefly to the tuberculin technique we have employed among healthy subjects at about 20 years of age.

A clinical case, recently observed, appears to support our view.

A nursing probationer, on enrolment at Ullevaal Hospital gave on two successive occasions (each with two scarifications) a completely negative response to the Pirquet test (Sept 5th–7th and 7th–9th, 1936). A third tuberculin test by the Mantoux method with 1 mg tuberculin (Sept 9th–11th) gave a reaction with 12 mm erythema and 10 mm induration. She began work in the tuberculosis wards on Dec 22nd 1936. On Jan 26th, 1937 she developed erythema nodosum and a Pirquet test on Feb 25th now gave a vesicular reaction with 25 mm erythema and 10 mm induration. A radio gram taken on Feb 26th showed a small isolated opacity in the left infraclavicular region and the blood sedimentation rate on Feb 28th was 44 mm in 1 hour. There can be little doubt that this patient's Mantoux reaction showing 10 mm induration was non specific and that the erythema nodosum was evidence of a primary infection.

CONCLUSION

When by any method of investigation we wish to draw a line between two biological groups or conditions, such dividing line is always more or less arbitrary, in reality there will be some overlapping of the two groups in the region of the dividing line. We should therefore rather reckon with a dividing zone than a dividing line, but in practice it may be

necessary to draw a sharp line, and, in our material, this line should therefore lie between 2 and 3 mm. Induration after the first Pirquet test, a repeated tuberculin test does not as a rule appear to reveal any additional infected individuals unless it gives a very powerful reaction. All this applies to human infection, which is, practically speaking, the only type existing in Norway.

It therefore appears that in our Norwegian student material, so far from obtaining too few positive reactors as our critics assert, we have included too many.

INHIBITION OF THE GONADOTROPIC ACTIVITY OF THE HUMAN PITUITARY BY ANTISERUM

By I W ROWLANDS, Ph.D.

AND

A S PARKES, Sc D Camb, F R S

(From the National Institute for Medical Research,
London, N W 3)

THE prolonged injection of thyrotropic or gonadotropic extracts of ox anterior pituitary tissue into laboratory animals leads to their becoming gradually insensitive to the stimulating action of the extract and may even cause a condition of hypopituitarism such as is found after hypophysectomy (Collip 1934). This result was originally ascribed to exhaustion of the responding gland, but in 1934 Anderson and Collip showed that the blood serum of an animal chronically treated with thyrotropic extract would protect a second animal from the effect of the extract. The same thing was afterwards shown for gonadotropic extracts. These remarkable observations subsequently confirmed by other workers, have opened up wide fields of research.

The mechanism of the production of the anti thyrotropic and antagonistic substances is not understood. It may be said definitely that their site of origin is not the responding gland, since Oudet (1937) has recently shown that antithyrotropic activity can be evoked in the thyroidectomised rabbit. Probably no endocrine organ is involved. A recent attempt (Sulman 1937) to associate the phenomenon with Abderhalden's "protective ferment" does not appear promising. The most probable explanation is that the active substance or grouping is linked with a protein having antigenic properties and that the production of antihormone activity is an immunological reaction. If so, by analogy with thyroglobulin, further work may lead to the separation of the prosthetic group from the protein and to the production of active but non antigenic preparations. The antibody theory is supported by the fact that the activity of the antisera can be concentrated in the globulin fraction—Thompson (1937a) states that all the activity appears in the pseudoglobulin fraction of the antiserum, but this may vary with the species of the donor. The theory is further supported by Thompson's observation (1937b) that the continued injection of sheep pituitary extract into a sheep does not lead to its serum acquiring the power to neutralise the action of the extract on another animal. By Twombly's failure (1936) to find antihormone activity in the serum of a woman chronically injected with an extract of human urine of pregnancy, and by Katzman, Wade, and Doisy's analogous work on the rat (1937).

These results agree with our own experience, and almost exclude the possibility that antihormones of the kind produced experimentally play any part in the maintenance of the endocrine balance of the normal animal. It is as yet uncertain what degree of zoological relationship between the species from which the extract is made and the chronically injected animal is compatible with antihormone formation. Apparently a wide divergence may be required since ox pituitary extract does not seem to evoke a strong response in a sheep or pig pituitary extract in a goat.

There are other aspects of the specificity problem such as species specificity and source specificity in the effectiveness of antisera. It is known that sera of animals immunised to ox or sheep pituitary extracts will inhibit gonadotropic extracts of the pituitaries of several different species but the full range of effectiveness has not yet been investigated. Sources of gonadotropic extracts include pituitary human urine of pregnancy human placenta and equine pregnancy serum. It is likely that considerable immunological specificity will be shown between the substances from these different sources. Thus anti-serum to extract of human urine of pregnancy is not effective against ordinary pituitary extracts while antiserum for ox pituitary is only partially effective against extract of human urine of pregnancy (Rowlands 1937). Antiserum to gonadotropic extract of pregnant mare serum appears to be only partially effective against other types of gonadotropic substance (Thompson and Cushing 1937). One of us (I W R) has examined the interaction of many antisera and gonadotropic extracts and the results will form the subject of a detailed report.

For clinical application it is important to produce antisera capable of neutralising human thyrotropic and gonadotropic substances. Fluhmann (1935) was able to obtain serum from a number of rats immunised to human pituitary but such a technique would be impracticable on a large scale, and the problem is to find what antisera capable of being produced in bulk are effective against the gonadotropic or thyrotropic substances of human pituitary. We have not yet been able to prepare sufficient amounts of human thyrotropic extracts to test antithyrotropic sera but it is hoped to do so eventually. Human pituitaries however prove to have high gonadotropic activity and a comparatively small number have provided adequate material for quantitative experiments.

It has been found that rabbit antisera to ox and horse gonadotropic extracts are at least partially effective against the gonadotropic activity of human pituitaries, but this fact is at present only of academic value since extracts of ox and horse pituitaries are highly impure available only in limited amounts and doubtfully antigenic in animals large enough to provide adequate amounts of serum. Clinical possibilities are however suggested by the experiments described below which show that serum from an animal immunised to gonadotropic extract of human urine of pregnancy will obliterate the gonadotropic effect of human pituitary extract on test animals.

METHODS

Antiserum to gonadotropic extract of human urine of pregnancy was prepared by subcutaneous injection of a 40 kg goat with 10 mg rising to 20 mg (1000-2000 rat units) daily of Pregnyl for five months. The response of the immature rat ovary as judged by weight was used to measure the activity of the Pregnyl and the effectiveness of the anti serum. Groups of ten rats (40-50 g) were given five daily

injections and killed 24 hours after the last one. The antiserum and the Pregnyl when given simultaneously were injected on opposite sides of the animal. The ovaries were weighed after fixation in Bouin's fluid. The ovaries weigh 10-12 mg without treatment a total of 0.25 mg of Pregnyl caused increase to about 35 mg which is slightly less than the maximum average size (40 mg) obtainable in this period by urine of pregnancy extracts (Deaneley 1935).

When the goat had been injected for three months 0.125 c.c.m. of the antiserum was capable of inhibiting that amount of urine of pregnancy extract required to give 35 mg rat ovaries. Assuming the goat to have had 1.5 litres of serum its total antigonadotropic power equalled 30 g of Pregnyl—i.e. about 20 times the amount administered over the three months. It has been found (unpublished data) that this anti-gonadotropic activity can be quantitatively recovered in the globulin fraction of the antiserum.

EXPERIMENTAL RESULTS

The anti-Pregnyl serum known to inhibit gonadotropic material from pregnancy urine was tested against placental gonadotropic extract and found to be effective. The crucial test against human pituitary

Capacity of anti-Pregnyl serum to inhibit the gonadotropic activity of a constant dose of 3 mg desiccated human anterior pituitary tissue

gonadotropic extract was then carried out. In a preliminary experiment on oestrous rabbits a saline extract of 10 mg. of fresh human pituitary caused ovulation in every one of a batch of ten rabbits. The same amount given with 2 c.c.m. of the anti-Pregnyl serum failed to cause ovulation in any of ten rabbits of another group. In an experiment on immature rats a saline extract of 25 mg. of human pituitary caused hypertrophy of the ovaries to an average of 70 mg. in a group of ten rats while one of 20 mg. given with 0.5 c.c.m. antiserum failed to alter the average weight which was normal at 10 mg.

It was decided therefore to construct a dose response curve for the power of the anti-Pregnyl serum to inhibit human pituitary gonadotropic substance. For this purpose a mixed batch of acetone desiccated pituitaries was prepared. A total dose of 3 mg. of this powder suspended in distilled

¹ The pituitaries used were from three accident cases in males and one female with grossening from 61 to 17 cm. Such pituitaries are about three times as potent as those from people under 45.

water, given over five days to a group of ten rats, was found to produce a very strong response (90 mg ovary weight). The same dose, together with varying amounts of the globulin fraction of the antiserum, was then given to further groups of rats. From the results shown in the accompanying Figure it can be seen that a total dose equivalent to a little over 0.05 ccm of the original antiserum inhibited the total activity of the 3 mg of human pituitary. The weight of the average human anterior pituitary after acetone desiccation is about 50-70 mg so that 1 ccm of the antiserum would inhibit the whole of the gonadotropic activity of one human pituitary.

It is impossible to say what the relation may be between content and output of gonadotropic substance in the human pituitary, but it is known that antiserum may be effective against the secretions of an animal's own pituitary (Parkes and Rowlands 1936, Rowlands 1937), and the above results indicate a strong probability that the gonadotropic activity of the human pituitary *in situ* might be inhibited by adequate amounts of the anti-Pregnyl serum and that a temporary, differential, serological "hypophysectomy" might be performed.

DISCUSSION

The interest of the above results lies in the possibility of successfully treating hyperpituitarism. The preparation of highly active extracts of ovary, testis, and pituitary may make it possible to deal adequately with conditions resulting from the hypofunction of these glands, but the hope of dealing with hyperfunction by endocrine therapy has seemed less good. Now, however, it seems that excessive secretion of the gonads or pituitary might be treated by passively immunising human subjects against their own pituitary hormones. Such a procedure would have great advantages over surgical interference in that the duration of the effect could be regulated, and the obliteration of pituitary activity would be differential. The serum described above would neutralise only gonadotropic substances, but further research may make available selective antisera for the thyrotropic and possibly other pituitary secretions.

SUMMARY

Prolonged treatment of a goat with urine of pregnancy extract (Pregnyl) resulted in its serum acquiring the power to neutralise, in test rats and rabbits, not only the effect of the original antigenic extract but also the gonadotropic activity of human anterior pituitary.

The activity of the serum was such that 1 ccm would inhibit the gonadotropic power of a whole human pituitary.

Our best thanks are due to Dr P. Hartley who prepared the globulin fraction of the serum, to Major G. W. Dunkin who undertook the immunisation of the goat, and to Dr Dorothy Russell who kindly obtained the human pituitaries. We are also indebted to Organon Laboratories Ltd. for the generous supply of Pregnyl.

REGIONAL ILEITIS CROHN'S DISEASE

By JOHN C. HODGSON, M.D. Edin

HONORARY SURGEON TO ASHFORD HOSPITAL, KENT

THE reading of an article on Crohn's disease (Hurst 1936) has been illuminating in the reconsideration of a diagnosis made seven years ago.

In 1932 Crohn of New York drew attention to a not uncommon intestinal condition looked upon in the past as a hyperplastic tuberculosis of the lower ileum and caecum. He described the clinical picture and demonstrated that it was definitely not tuberculous. The morbid anatomy is that of an inflammation of the terminal ileum which may spread to the caecum, the affected segment becomes thick and oedematous and rigid, and this is followed by fibrosis and progressive diminution in the lumen of the rigid bowel. In the inflammatory phase adhesions and fistulae may develop, and although microscopically giant cells are found, yet no tubercle bacilli have ever been discovered and animal inoculation is negative. The clinical picture is one of progressive obstruction of the small intestine.

Since then numerous papers have appeared in America on the subject (e.g., Rosenblate, Goldsmith, and Strauss 1936, and Koster, Kasman, and Steinfield 1936) but the condition is only becoming recognised in England. Cases have recently been recorded by Dickson Wright (1935), Edwards (1936), Barbour and Stokes (1936), and Jackman (1934). A good account has been published in Holland by Snapper, Pompen, and Groen (1936), but Crohn's disease is apparently still unrecognised in other parts of the Continent.

Seven years ago a man aged 51 came under my care suffering from intestinal obstruction and at operation the provisional diagnosis of an inoperable carcinoma invading the ileum and proximal caecum was made. A lateral anastomosis was performed "to tide the patient over." He rapidly improved, put on 2 st in weight, and did a labourer's work and was lost sight of. Recently he came under my care again, suffering from a perforated duodenal ulcer, from which he is now recovering.

Hurst's paper had just been digested and this recently acquired knowledge, with fresh radiographic evidence, suggests that Crohn's disease was the probable diagnosis. A brief résumé of the case is therefore given in the belief that it may be useful to others who may meet with a similar condition.

CASE HISTORY

For 18 months the patient, aged 51, had complained of attacks of pain in the lower right segment of the abdomen. These attacks lasted about a week, often passed off for a few weeks. The pains were gripping and accompanied by distension—he became "blown out." His bowels alternated between constipation and diarrhoea, but especially the former and castor oil was the only medicine which would help him. Occasionally he vomited, his appetite was poor, and he had lost weight.

He was admitted to hospital, and the operation notes state: "Partial obstruction due to a bloodless band over the caecum, and partial volvulus from this. Appendix removed and band cut, nothing else abnormal found." After this operation he had five months freedom from all symptoms. Unfortunately, they returned, and twelve months later he came under my care. The pains had occurred more frequently, especially about one hour after meals, and in the right iliac fossa. His appetite had become poor, he was afraid to eat because of the pains food caused, and he had lost about 2 st in the last year, and actually 1 st in the last six weeks. For the

last six months his constipation had wholly disappeared, and he had instead three to four diarrhoeic motions per day. He vomited occasionally he had never been jaundiced, and he had never passed blood.

Examination.—A thin anæmic patient with abdomen distended in centre and flanks. Umbilicus stretched and bulging; visible peristalsis present of the small intestine type with loud rumblings. Some rigidity in right loin no mass felt; abdomen very resonant occult blood + Mild pyrexia present.

Radiography.—Great dilatation of the small intestine indicating an obstruction of the lower ileum and ileocolic valve. Unfortunately this plate was destroyed so no comparison is now possible.

Operation.—A large inoperable mass was found invading the terminal ileum and adjacent cæcum and the diagnosis of carcinoma was made. The naked-eye appearance did not suggest tuberculous. The ileum above this was very greatly distended almost to the diameter of the normal stomach. The mesentery was thickened and the mesenteric glands enlarged. A lateral anastomosis was made between the cæcum and the ileum above the growth. Recovery was uninterrupted.

At the recent operation the cæcal area could not be palpated for adhesions, and his general condition made speed imperative. Further radiography shows some remaining dilatation of the small intestine anastomosis satisfactory; filling defects in the terminal ileum and proximal cæcum

amounting to the string sign—a thin irregular linear shadow running through the filling defect. This string sign is described as very characteristic of the disease.

DISCUSSION

Crohn's disease seems to be the correct diagnosis in this case. The treatment usually advised in this condition is total excision of the affected segment since the disease tends to spread if not eradicated but this case suggests that simple short circuiting is sufficient in certain cases and should be seriously considered when the infiltration of the mesentery renders total excision dangerous.

My thanks are due to Dr E. Scott who did the radiological work in this case.

MEDICAL SOCIETIES

WEST LONDON MEDICO-CHIRURGICAL SOCIETY

A MEETING of this society was held on April 9th Mr N. F. SINGLAIR, the president, being in the chair when a discussion on

Sudden Death

was opened by Dr B. T. PARSONS-SMITH. He said that as a general rule the cause of a sudden death could only be a matter for speculation until a post mortem examination had been made but that some times the patient's previous medical history might afford valuable evidence circumstantial evidence might be enough to justify a reasonably safe opinion when for instance, death followed a massive hemorrhage in a patient known to have been suffering from an aortic aneurysm or if it followed hemorrhage after operations or obstetrical accidents. Chronic disease did not necessarily explain sudden death. Sir William Osler had said: "It may seem paradoxical but there is a truth in the statement that persons rarely die of the diseases with which they suffer. In cases of sudden death a post mortem examination should be deemed necessary however convincing the circumstantial evidence." The speaker then discussed those cases in which the death was incidental to natural causes—i.e. when an acute or chronic disease ended fatally in a sudden and unexpected fashion. According to Glalster 1 per cent. of all deaths from natural causes were sudden and statistical evidence associated most of these with varying types of cardiovascular disease. The risk of sudden death was great in such conditions as aortic valve disease, specific aortitis, angina pectoris, coronary atheroma and myocarditis, both acute and chronic. The sudden syncope had been attributed to vagal inhibition but Lewis doubted whether permanent syncope could be produced in that way. Sudden death was nowadays associated with ventricular fibrillation which might develop in all types of human heart disease notably in digitalis toxæmia now fortunately less common than it once was. Fibrillation was also thought to be the immediate cause of sudden death following

straightforward fainting or vasovagal seizure and was probably the explanation of the fatalities which sometimes followed trivial accidents, sudden shocks and painful stimuli.

Hæmorrhage, arterial embolism and thrombosis were foremost among the vascular accidents which might have immediately fatal results. Pulmonary emboli deserved special mention because of their frequency and high fatality rate. Those coming from venous clots probably were more often fatal than not, while the relatively small emboli from intracardiac sources unless complicated in some other way were seldom fatal. Emboli of the major circuit, which arose most often from infective endocarditis and failure of the left heart might lead to sudden death, commonly by entering the cerebral or coronary arteries. Fatal results had also been recorded from their entering mesenteric and supra-renal vessels. Thrombosis apart from embolism might cause sudden death when it occurred in the heart or brain.

Dr EDWIN SMITH, coroner for the western district of London, said that coroners often found that post mortem examinations had been carried out too inadequately to ascertain the cause of death for instance sometimes the coronary or cerebral arteries had not been looked at. Neglect to open the stomach might lead to the concealment of important evidence for example in one case recalled by Dr Smith of sudden death during anaesthesia the anaesthetist had reason to be grateful to the pathologist who found 2 lb. of fæces in the stomach. Other examples of inadequate autopsy were a hæmorrhage while quietly at work had died suddenly the doctor had reported death as due to a fractured skull and suggested she had hit her head against a wall as she walked to work. On further inquiry the fracture was found to have been made at autopsy and death had been due to a stroke. In another case a small handkerchief rolled up at the back of the pharynx had not been found at autopsy and only came to light in the dissecting room.

Dr Smith thought a distinction should be made between deaths due to an anaesthetic and those occurring while under an anaesthetic. The legal

compulsion to notify a coroner of a sudden death was on the registrars and there was no law compelling a doctor to report the cases direct to the coroner. In practice, however, the coroner came to the coroner doctors to report direct to him cases which were bound to come to his notice. The mental state was sometimes very important in determining sudden death, for example in people with hardened arteries who had to make an after dinner speech. Dr Smith mentioned that he did not accept acute gastritis as a cause of death without amplification. In his district the registrars were required to report such certificates to him at once in order that the underlying cause of the gastritis should be ascertained. In conclusion he described the case of a man found dead in a cottage which had been struck by lightning, about half an hour before the storm, a man, known to have been on bad terms with the dead man, had been seen leaving the cottage. The jury solved a difficult problem by a verdict that the man had died 'from a visitation from God under suspicious circumstances'.

Dr T SKENE KEITH had analysed the last 800 cases of sudden death investigated by him and had found the following percentages from various causes: cardiovascular disease 60, pulmonary disease 6, diseases of the intestine 25, diseases of the central nervous system 15, renal disease 05, special conditions 6, stillborn 05, external agencies 21. For statistical purposes sudden death should be defined, and he would define it as a death which so surprised the doctor that he was not prepared to sign a certificate or when a certificate so surprised the registrar that he did not accept it or when death so surprised the patient that a doctor had not been called in. Deaths from surgical operations came under three headings. In the first group the patient had not the strength to stand a necessary operation either because the operation was too severe, for instance an abdomino perineal excision, or because the patient was already too reduced, as in advanced acute peritonitis. In the second group death was due to surgical misadventure. Those of the third group were due to status lymphaticus, a condition repeatedly declared dead but one which Dr Keith believed to exist, it was certainly found in anæsthetics frequently among children dying under anæsthetics than among those dying from road accidents. Deaths from external injuries included those due to birth injuries which were nearly always due to tentorial tears, these seemed to be found as often after natural and easy labours as after difficult and forceps deliveries. Dr Parsons Smith had said how much the doctor might miss the aid of autopsy in diagnosis, the pathologist might miss still more the doctor's contribution to the history. The number of cases coming to autopsy in which the doctor was to blame was remarkably small. The pathologist was not absolutely infallible, just as it was much harder to diagnose a fault in a car that would not start than in one that was running badly. The pathologist was up against the difficulty of lack of function. He could only say that he had seen similar appearances before and that they were compatible with cessation of life. While a definite opinion could usually be given on coronary occlusion or atheroma it was much harder to decide whether myocardial degeneration was a cause of death. Dr Keith was in the habit of looking in the stomach of these cases just to make sure. Ventricular fibrillation was a comfortable explanation as it allowed the heart to die at any time, it only shifted the burden of proof on to someone else. Death in heart cases was apt to be so sudden that at the Heart

Hospital, it was unusual for the resident medical officer to get to the bed in time. Dr G S HOVENDEN mentioned four cases of death in the puerperium, two of which he had signed up as due to air embolism and two to pulmonary embolism, he had been unable to decide which was the cause.

Mr H L ATTWATER had been struck by the comparative frequency of sudden deaths during comparatively trivial operations.

Mr G B WOODD WALKER had recently come across a museum specimen of a ruptured aneurysm of the circle of Willis which had occurred in a window cleaner. The pathologist had established that the rupture had occurred before the man had fallen off his ladder, the specimen had impressed upon him the importance of post-mortem examination especially in these days of compensation.

Mr J KEMBLE thought that patients dying on the operating table and those dying of post operative pulmonary embolism were alike in being of the sub thyroid type, sudden death of this kind was not so common among patients who had had pre operative thyroid therapy.

Dr GERALD SLOT pointed out the difficulty a pathologist had in coming to any conclusion about the state of the lungs after artificial respiration had been carried out for, say, half an hour. He had recently examined the body of a woman, found with a lysol douche beside her, in whom death had occurred without intracervical interference, such deaths were apparently quite common although douching in other circumstances was without risk. Coronary thrombosis, one of the commonest causes of sudden death in adult men, apparently occurred much more often than it used to do. Dr Slot spoke of the difficulty presented by the increasing number of undetectable poisons and the desirability of having a panel of medico legal experts to perform autopsies. Mr LEVY, speaking as a barrister, complained that doctors would use terms incomprehensible to the magistrate, lawyer, and jury.

Dr PARSONS SMITH, in reply, said the apparent increase in coronary thrombosis was due to its better recognition. Dr EDWIN SMITH said both the use of and the objection to medical terms were reasonable, he told how at an inquest on a man who had been shot in the sternum, the foreman of the jury had concluded that the man must have been running away. Dr SKENE KEITH, in reply to Dr Hovenden, said that the distinction between air and pulmonary embolism could have been made by autopsy.

ROYAL SOCIETY OF MEDICINE

SECTION OF PSYCHIATRY

At a meeting of this section held on April 13th, the chair was taken by Dr T A ROSS, the president, and Dr C P SYMONDS read a paper on

Mental Disorder following Head Injury

He confined himself to cases of closed injury—i.e. those without compound fracture—and omitted all focal lesions and traumatic epilepsy. The outstanding feature, he said, was loss of consciousness in some degree, if a man subsequently forgot what he had done he could be assumed to have been unconscious during the period of traumatic amnesia. The picture in concussion was dominated by the physical state of collapse, the mental state was one of profound stupor, from which the patient recovered

in a period of varying length. He might remain for some time in a state of automatism or this state might come on after an intermediate period of consciousness. Or recovery might take days, weeks or months constituting a state which resembled Korsakow's psychosis. It was these cases which afforded opportunity for detailed analysis of the acute traumatic psychosis. The prognosis was always good. A regular sequence of symptoms could be observed. They had been described as first the stupor then deep clouding of consciousness with resistances; clouding of consciousness with bewilderment and finally Korsakow's condition. All were included in the amnesia and it was better to treat the state as a whole, noting successive stages in which predominated stupor, confusion, and defective memory for recent events with tendency to confabulation. The stupor was accompanied by restless bodily movements and absence of response to stimuli except the deepest alimentary and protective functions. This state rarely lasted more than a few days. The patient then became excited and restive, he was wet and dirty and had to be fed and was sometimes delirious. This lasted for days, weeks even months with occasional relapse into stupor. When he began to be accessible he showed profound disorientation in space and time, defect of perception, memory and judgment, perseveration, disturbance of speech function, tendency to interpret events in the light of long past experiences, and very far reaching retrograde amnesia. There was a tendency to confabulate. The difficulties in perception played a large part in causing confusion as did also perseveration and the difficulty of distinguishing the figure from the background in the thought process. There was raised threshold and over reaction as in lesions of the sensory pathway at any level. Performance was unduly influenced by external events. Perseveration in thought, word and deed was a striking feature. Speech disturbance might be so prominent as to suggest a focal lesion but was only part of the general mental disorder. After the first return of automatic speech there was often a rush of jargon talk then the talk began to have direction though meaningless. At this stage the attention could be gained for a minute or two but responses were so little related to the requests as to appear to be at random.

An interesting illustration was afforded by the response of a patient to the written command. Under the second button of your jacket and do it up again. He had seized the correct button and fiddled with it but got no further and then asked: I rather wondered if you meant your second jacket or my second jacket? Was it your bottom you meant or my bottom? This threw some light on the basic confusion of thought which characterised the state. A month later he had appeared perfectly normal and he had since returned to work. Response to written commands returned more slowly than to spoken commands because it was more difficult to grasp the written sentence as a whole.

The transition to the Korsakow state was gradual. A tendency to confabulation continued when confusion had gone. It might lead to false accusations in relation to the accident. Gross defect of recent memory might remain the outstanding symptom for a long time. The mood affected the symptoms, elated easy going people confabulated readily. Sometimes the mood was indifferent; sometimes there was petulant childlike depression but elation was more usual. The end of the Korsakow stage was not clear cut. The patient of ten showed no insight, its

return was an important landmark. The longest record was that of a man of 67 who showed confusion and defective memory fourteen months after the accident but was well a month later. Age was not a bar to good prognosis. The pathological changes must be reversible to the extent of allowing restoration of function. The amnesia remained absolute for the stupor and confusion and patchy for the Korsakow stage.

POST TRAUMATIC DEMENTIA

In minor injuries the whole sequence was run through in a few minutes and in minimal injuries some stages were omitted. Some patients showed residual injuries which might be in some degree permanent. There was no relation between the duration of the traumatic amnesia and the severity of this post-traumatic dementia. Possibly it was due to coarse lesions slow to resolve and to some extent irremediable while the underlying condition in the traumatic psychosis was a molecular change easily reversed. The chief symptoms were alterations in mood, judgment and memory and scattered amnesia. The mood changes were often exaggerations of pre-existent traits. These symptoms varied with the age and constitution of the patient and with environmental stresses. This was in contrast with the acute condition which was rather an impersonal affair. Children showed behaviour disorders like those following encephalitis lethargica. Intellectual impairment was commoner in patients over 45. Patients of manic-depressive stock were especially liable to an attack of this disorder after an injury. Under any stress these patients tended to become sleepless, anxious and irritable. All tended towards recovery and residual disability was very rare apart from coarse lesions. Dr Symonds had noted he said of only two cases with permanent disability and both had had a previous head injury with apparent recovery before the causative accident. A persistent long retrograde amnesia indicated serious damage.

Injury might precipitate paranoia, schizophrenia or manic-depressive insanity by exaggerating previous traits and by creating a state of invalidism to which the patient reacted according to his style. There seemed to be a special liability of this kind in manic depressives. Symptoms might appear during the confusion of the traumatic psychosis.

Traumatic neuroathenia as loosely used covered three groups of patients: those who suffered from psychogenic hysterical or anxiety states; those really suffering from post-traumatic dementia; and those whose constitution was of the depressive or anxious type and in whom the injury released a condition which ran its course usually towards recovery.

Attempts had been made to explain the pathology in terms of increased intracranial pressure or sub-arachnoid hemorrhage but lumbar puncture often revealed a perfectly normal cerebrospinal fluid. The only conception of pathology left was the old one of direct molecular damage. The late effects could only be properly understood in the light of a full psychiatric study of the patient. It was not only the kind of injury that mattered but also the kind of head.

DISCUSSION

The PRESIDENT described his own experience of slight concussion due to a riding accident. He remembered his arm round the horse's neck then a dream state of which he had many memories and finally he came to in a farmhouse. He remembered a cold familiar but unplaceable landscape and a

babble of voices over his head, then he was on and off a horse, then he saw a haystack of which he hated the colour, then he walked and talked most politely with a young man. Actually his niece, who was with him, reported that he had sat on the ground saying repeatedly that it was bloody cold. She and a young man had tried to replace him on the horse and to get him sheltered behind a haystack. The selective memory was interesting. He wondered if the patients really had amnesia, or if rather they had dream memories, consecutive but inconsequential.

Dr T TENNENT reported on 44 patients admitted to the Maudsley Hospital between 1923 and 1936 who had stayed in from two months to two years. Eighteen of them had been admitted between 1933 and 1936. Four had proved to be general paralytics. The remainder had shown the symptoms described in the paper. In some, hallucinatory experiences and bizarre ideas became prominent as the confusion disappeared and none of these had recovered. Two had developed a manic reaction and five a depressive one. Children had shown moral change and intellectual deterioration. In 25 cases the form seemed attributable solely to the accident, all had marked memory impairment, six being of the Korsakow type. Some ex Service patients maintained the war was still on. All this group had recovered enough to be discharged and 22 had been followed up. Ten had remained well, nine were improved but had residual symptoms, two were in mental hospitals, and one was dead.

Prof E MAPOTHER thought that amnesia could not be identified with unconsciousness. He himself had had a concussion while playing football, a little after half time he had suddenly found himself playing in the opposite direction to the one he last remembered. He had assumed he had had a kick in the first half and played automatically but was now not sure whether the kick had not occurred immediately before "waking up" and he had suffered from retrograde amnesia for 10 or 15 minutes. The gradual emergence from coma was a most important study. He had seen the sequence, described by Dr Symonds, passed through in about an hour by a pedestrian knocked down by a car. There seemed a strong tendency to an orderly sequence.

Mr HUGH CAIRNS remarked on the extraordinary persistence of this reversal process, with ultimate recovery. He had seen symptoms start five days after an injury, coinciding with the onset of sepsis and cellulitis, and disappear as they cleared up. Symptoms might also coincide with the exhibition of barbiturate drugs. There must be a great deal of compensation going on, so that the patient could cerebration until some extra factor, like sepsis or drugs, complicated his state. He had known a patient write out his delirium afterwards, it had tallied with the ramblings noted at the time.

Dr W F MENZIES protested against the misuse of the term Korsakow's psychosis in the absence of peripheral neuritis, on which Korsakow had insisted. He recalled three pre-war cases. One patient had been able to repeat fifty lines of the *Odyssey* at a time after being hit by a boom, he had never looked at Greek since leaving school twenty years before. A second patient, a dement had fallen twenty feet on to asphalt and had suffered a fractured skull with permanent second and third cranial nerve paralysis, but had otherwise recovered rapidly and been no more demented after than before but became very bad tempered. This indicated molecular change. Compound fractures turned epileptic or very bad tempered because there had been fibrotic changes

and new blood vessel formation. The third had developed cerebral abscess three weeks after colliding with a lamp post, the surgeon had seen traces of meningeal disturbance when operating and had described the case in THE LANCET as "general paralysis without symptoms". The patient had completely recovered, but had a persistent difficulty in recalling proper names.

Dr E GUTTMANN described work on twilight states in boxers. The transient disturbance of consciousness through knock out was functional, post concussional delirium suggested organic lesion. Some boxers felt the knock out, some had seen it coming, others forgot the whole round.

Dr A W PETRIE referred to analogous alcoholic states, and asked whether all speakers meant the same thing by post traumatic dementia. Possibly the term might be confined to those who passed into permanent true dementia after injuries, and not applied to post traumatic instability.

Dr CLIFFORD ALLEN mentioned Janet's views on the structure of consciousness and said that patients had repetitive dreams with terror that something dreadful was about to happen. Accidents might be unconscious attempts at suicide in manic depressive personalities.

Dr PURDOY MARTIN said he grouped symptoms into amnesias, neuroses, negative symptoms, such as disorientation and confusion, positive release symptoms, such as restlessness, talkativeness, and noisiness—many of these patients had haemorrhage in the cerebro spinal fluid and all showed increase of protein—and late dementias. Some patients went into dementia after apparent recovery, and the good prognosis must be qualified by this fact. Observers had recently been finding excessive gliosis, especially in the frontal lobes. Elation was often present, it was to be regarded as a focal symptom, for it was often seen in frontal lobe lesions. It was associated with the symptom of jocularity and nearly always persisted throughout the illness. It might prevent realisation of headache and other symptoms.

Dr HENRY WILSON spoke of the relationship between the psychosis and the duration of confusional symptoms. The confusion might be enough to send a schizoid personality into schizophrenia. Great unhappiness and anxiety might be caused by it.

Dr SYMONDS, in reply, agreed that the patchy amnesia left a dream like memory, the termination of traumatic amnesia was not abrupt. The high proportion of residual disability in Dr Tennent's series might be related to the greater environmental stress in the hospital class and the different standard of employability. Retrograde amnesia was very brief—not usually more than half an hour. One patient had suffered a return of confusion on an attack of cystitis, the influence of sepsis was important. The post-traumatic dementia was not a mere instability but included a real failure to retain. Elation might accompany organic lesions in various parts of the brain.

NATIONAL BIRTH CONTROL ASSOCIATION.—A medical conference of this association will be held at 7, Drumsheugh gardens, Edinburgh, on Friday, April 30th. At 3 P.M. Mrs Helena Wright, M.B., will open a discussion on the technique of contraception, and at 8 P.M. Mr J R Baker, D.Phil., lecturer in cytology in the University of Oxford, will speak on recent advances in the scientific study of chemical contraception. Further information may be had from the headquarters organiser of the association, 26, Eccleston street, London, S.W.1

REVIEWS AND NOTICES OF BOOKS

Textbook of Medicine

By CHARLES PHILLIPS EMERSON M.D. Research Professor of Medicine Indiana University Assistant Professor of Medicine Cornell University (Ithaca) London: J. B. Lippincott Company 1936 Pp 1290 30s.

THE issue of a large new text-book of medicine prompts the question Is there something here that is not to be found in the standard books? One answer here is that Prof. Emerson has tried to set the clinical behaviour of disease in the forefront of his presentation. The incidence and the symptoms and signs of a disease come early in its description being the basic facts of medicine morbid anatomy bacteriological and biochemical findings follow on so that it may be seen just how far they elucidate disease—and how far they fail to do so. This is no fundamental departure from the common sequence but rather a shifting of emphasis, setting less store by the contributions of laboratory science and showing how medicine is still in great part a lore of disease and an art founded on generations of experience. Another answer is that this book is a bigger one than most of its fellows. The clinical descriptions are comprehensive and little historical sketches and even biographical notes on great men are included. Modern scientific work relevant to each subject is not ignored but is cited, often in smaller type or as a footnote and reference is made to important original publications.

The authors style has character to it he is always clear and succinct but is fond of tricks of inversion and apposition whose slightly stilted effect is often rather telling. Choice of type and general arrangement are good but misprints usually mix takes in spelling are numerous enough to be irritating. There are no illustrations. An immense labour must have gone to the writing of a book so fully documented and much of that labour has, in the nature of things, been spent on books rather than on patients. This leads inevitably to some distortions of which the statement that in the diagnosis of pulmonary tuberculosis when the clinical findings are inconclusive the X ray pictures are likely to be even more so is a surprising example. But it is clearly impossible in these days for a text-book of medicine to be informed throughout by detailed first hand experience. Few could have performed so well as he has the task which Prof. Emerson set himself and many students qualified and otherwise should find his work of great value.

L'infection bacillaire et la tuberculose

Fourth edition By A. CALMETTE. Revised by A. BOQUET and L. NÈGRE. Chefs de Service à l'Institut Pasteur de Paris. Paris: Masson et Cie 1936 Pp 1025 Fr 175.

Calmette made many contributions to the study of tuberculosis in the course of a busy life but probably none was more brilliant than the text-book which has now reached its fourth edition. Its well balanced exposition of the subject its breadth of outlook and its lucidity of expression have all contributed to make this work classic. Dr A. Boquet and Dr L. Nègre in their revision have been mindful of the tenets of their late colleague and have brought the work up to date without deviating from

the original point of view or changing the personal note. As far as possible footnotes indicate which of the two editors is responsible for the new material.

More than one hundred pages have been added and the book is now bound in a serviceable black cloth board cover which is a great improvement on the old paper one. The new sections include fresh descriptions of recent improvements in the clinical pathology of tuberculosis such as the technique of gastric lavage and various new culture media. Chapters have been inserted on the differentiation of human and bovine strains and on avian strains by Dr Boquet as well as a section dealing with the dissociation of colonies which is demanding much attention at the present time. Dr Nègre has enlarged the chapter on the ultra virus of tuberculosis whilst maintaining the general thesis concerning its existence. The sections dealing with BCG vaccine which was Calmette's last great contribution to the study of tuberculosis have been expanded to include new work. It must have been difficult, especially here, to know what to leave out and what to insert but it seems a pity that old statistics on the fate of children born in tuberculous households should have been used where modern figures are available—notably the figures quoted for London on p. 853 and for England on p. 949. These are but small blemishes in a book which has earned and will continue to earn the gratitude and respect of all students of tuberculosis. It is noteworthy that the only English version of this work is that which W. B. Soper and G. H. Smith translated from the second French edition and published in America in 1923. This new edition merits translation.

Towards Peace of Mind

By KARL M. BOWMAN M.D. Chief Medical Officer Boston Psychopathic Hospital, London George Allen and Unwin Ltd. 1936 Pp 278 6s.

THIS volume stands midway between a popular exposition and a text book suitable for students. Its outstanding virtue is to combine a sound appreciation of heredity and neurology with an accurate and dispassionate exposition of Freudian psychopathology. While numerous references are made to recent advances in the study of the nervous system and of the mind the aim of the book is never lost sight of and the pursuit of mental health is illustrated by theory, clinical examples and therapeutic advice. The book can be strongly recommended to all practitioners who want a scientific and human exposition of modern psychological medical aims.

Operative Surgery

Second edition. By ALEXANDER MILE M.D. F.R.C.S. Edin. Consulting Surgeon Royal Infirmary Edinburgh and D. P. D. WILKIE M.D. F.R.C.S. Edin. and Eng. Professor of Surgery University of Edinburgh. London: Humphrey Milford Oxford University Press. 1936 Pp 631 21s.

In this edition the text has been completely revised, and the revision has been done well. In all the main things the teaching appears to be sound but a few procedures might have been eliminated and naturally some advice is given with which all

will not agree. It does not seem necessary, for instance, to mention the use of bone chips or wax or sponge for filling a septic bone cavity. Again, for stopping a cavity in the head of the tibia the use of the gastrocnemius is more crippling than that of the sartorius. We are told (p. 121) that the shaft of the humerus can be exposed by an incision "made through the appropriate muscular interspace," without specifying what this space is. The omissions include that of the occipital approach to the fifth nerve. But the extraordinary amount of information given is nearly always good and is invariably sponsored by some eminent authority. No student up for a higher surgical examination will go wrong if he hands out the teaching of this book to his examiners.

Clinical Handbook for Residents, Nurses, and Students

Second edition. By Members of the Staff of St Vincent's Hospital, Sydney. Edited by V. M. COPPLESON, M.B., Ch.M., F.R.C.S., and DOUGLAS MILLER, F.R.C.S., F.R.A.C.S. London and Sydney: Angus and Robertson, 1936. Pp. 205. 6s.

THIS is a book of instructions for the medical student or the resident touching the hundred and one things that he must learn to do with his hands, such as sterilisation, use of needles, collection of specimens for pathological examination, giving anaesthetics, examination of urine, and so forth. It includes sections on the nursing and management of ophthalmic, ear, nose, and throat and gynaecological cases, the treatment of common skin conditions and of poisoning, preparations for X-ray examination, the use of plaster, and various other topics. Only the routine practice at St Vincent's Hospital is described, and the descriptions are simple, clear, sound, and practical, blood transfusion, for instance, is given with citrated blood, a funnel, and a tube, and no other method is mentioned. Not every hospital takes the trouble to see that its students are well trained in these routine matters of technique, and St Vincent's Hospital is to be congratulated on providing its residents, present and future, with such a comprehensive and workmanlike manual.

Fundamentals of Bacteriology

By MARTIN FROBISHER, Jr., B.S., D.Sc., F.A.A.S., Associate in Bacteriology, Johns Hopkins University. London: W. B. Saunders Co., 1937. Pp. 474. 14s.

EVER the bacteriological enthusiast, proud of his subject and convinced of its educational value might be staggered by the opening words of the preface of this little book. "With bacteriology in its present state of development, no one can be said to have acquired a complete cultural education who remains uninformed concerning the unicellular fungi of the class *Schizomyces*." This certainly argues a very broad or a very narrow conception of the "complete cultural education," it is hard to decide which. But the author's later modification of the statement that a knowledge of bacteria "not only increases one's general usefulness but greatly broadens his view of life and sharpens his appreciation of the subtlety of nature" is one that (barring its verbal construction) will be endorsed by everyone familiar with the subject. It is to introduce bacterio-

logy to the general but cultured reader that Dr Frobisher has written his interesting and accurate little book. The subject is well set out in historical perspective and the many activities of bacteria in nature beyond their pathogenic rôle are attractively described.

Within its scope it is one of the best introductions to general bacteriology we have seen and it is just the kind of book which a student of medicine who has become interested in bacteriology for its own sake might profitably read.

CORRIGENDUM—"What is Osteopathy?" The authors of this book, which received appreciative notice in our columns last week, are Dr Charles Hill, deputy medical secretary, British Medical Association, and Dr H. A. Clegg, deputy editor, *British Medical Journal*. Mr H. G. Wells contributes a preface.

NEW INVENTIONS

A NEW DOUCHING ATTACHMENT

THE douching attachment here illustrated has been designed with two objects in view. First, it provides a lotion carrier for use with a cystoscope, and so eliminates separate stands for holding such a reservoir, and secondly, the whole attachment can be sterilised. It is made to clip on to a lithotomy crutch, and its height can be adjusted. The funnel carrier is loose on the upright, and fitted with "dogs" to enable it to be maintained in any desired position. It is also a useful accessory in gynaecological work.

The apparatus has the advantage

of being portable, and can be used on any table that has a suitable lithotomy crutch pole. It has been made for me by Messrs Allen and Hanbury, London, W.1, to fit the St Bartholomew's operating table.

CHARLES E. KINDERSLEY, F.R.C.S.,
Surgeon to the Royal United and Royal
Mineral Water Hospitals, Bath.

THE LANCET

LONDON SATURDAY APRIL 17 1937

THE FUTURE OF OUR POPULATION

THE observant man can hardly be blamed if he has a feeling of bewilderment tempored perhaps by scepticism when he considers the figures relating to population. For years economists and other experts have made the spectre of over population dance before his eyes. He has been told that poverty and misery must be reduced by volitional control of the size of the family—that the 'planned' family is the ideal at which we must aim. There seems moreover ample justification for the argument. He knows that the population of our country has shown a phenomenal increase that it has multiplied nearly fivefold in rather more than a century and that it now depends largely upon distant sources for its food supplies. Looking even casually around him he seems to see additional evidence on every side: there is a continual encroachment of the town upon the country, building activity in every direction, town planning schemes in operation or visualised, traffic congestion on road and rail affecting his everyday life, depressing figures of unemployment, unsatisfactory diets amongst the larger families in the poorer strata of society and an annual excess of births over deaths so that the numbers in the country continue to increase.

And yet the expert now tells him that we are seriously threatened with depopulation. In the daily press and in books and pamphlets he is warned gravely that our population must shortly follow a downward path that unless people soon begin to have more children we shall be threatened with extinction that a Royal Commission ought at once to be appointed to discover the facts and to formulate a population policy.¹ What is he to believe? What is the explanation of the seeming paradox? An excellent attempt to answer these questions in simple terms has now been made by the Population Investigation Committee. This body formed last autumn under the chairmanship of Prof. A. M. CARR-SAUNDERS includes representatives of the British College of Obstetricians and Gynaecologists, the Medical Research Council, the Royal Economic Society, the Society of Medical Officers of Health, the British Population Society, the Eugenics Society and a number of medical and economic authorities. It was formed to examine the factors influencing contemporary trends of population in England and Wales with special reference to the fall of the birth rate. Its first task has been to consider the recent history of our population to determine how its prodigious growth has taken place, what effect the declining fertility rate is

likely to have upon its future size and constitution and what have been the basic causes of that fall in fertility. The results of these inquiries are set out in a pamphlet prepared for the committee by Dr. O. P. BLACKER and Mr. D. V. GLASS. When the population began to increase towards the end of the eighteenth century it is possible that there was some rise in fertility, but the evidence is scanty. Throughout the nineteenth century the rise was certainly not due to an increasing birth rate but to a falling death rate. Between 1838 and 1913 the births annually exceeded the deaths by about 300,000; in the decade 1914-23 the excess was only 220,000; a year in 1934 it had fallen to 121,000. Though there is likely to be an excess in 1937 it will be still smaller, and in another five years or less that excess will have vanished. One result of this falling birth rate is the raising of the average age of the population. In time this must lead to an increase in the crude death rate—although with further advances in medical science and public health the death rates at ages may continue to decline. A population that contains a large proportion of old people must have a relatively high death rate and it is on this rate, in conjunction with the fertility rate, that the growth of the population must depend. With an ageing population we clearly cannot depend upon favourable changes in the death rate to maintain our numbers. To take a simple example, Dr. G. F. McCLEARY has shown² that the effect on population growth of an entire elimination of infant mortality would be completely neutralised by a reduction in the birth rate of less than 1 per 1000. It is mainly on fertility that the future population must depend and although at present the birth rate remains higher than the temporarily lowered crude death rate it is now well below the replacement rate. It is in fact to this rate that we must look and the figures of the 1931 census of England and Wales show that persons aged 20-35 were more numerous than the young persons in the age groups 0-15; in other words there were in 1931 not enough young people to replace the men and women twenty years older than themselves. With the aid of a relatively new statistical technique the level of this replacement rate can be measured—by an index known as the net reproduction rate. Briefly this expresses the number of women who in the next generation will replace the women of reproductive age in this generation. In the words of BLACKER and GLASS:

If the women of reproductive age in this generation who are mothers of children are having sufficient girl children to replace themselves as well as the women of their age who are childless, the net reproduction rate is 1 or unity and the population is maintaining itself. If allowing for deaths they are not having enough girl children to do this the net reproduction rate falls below unity and the population is not replacing itself; if they are having more girl babies than is necessary

¹ The Future of Our Population. By O. P. Blacker and D. V. Glass. Issued by the Population Investigation Committee, 69, Leicestershire Square, E.W. 1. 1p. 31. 6d.

² The Science of British Depopulation. By G. F. McCleary. 31d. London: George Allen and Unwin, 1935. 17. 16d.

for this purpose, the net reproduction-rate is above unity and the population will increase."

Dr ENID CHARLES⁴ has calculated that in 1933 the figure for England and Wales was only 0.734, or according to the fertility- and mortality-rates of that year 1000 women of reproductive age were producing only 734 girl children who would grow up to replace them in the next generation. The figure is below unity in most of the countries of western Europe and, as McCLEARY emphasises, amongst the British born in the Dominions. It is easy, though laborious, to calculate the downward path along which this present position must lead us, and an example of the calculation, by Mr C. A. GOULD, is given on p. 944. Naturally the further ahead we endeavour to prophesy the more we may deviate from the truth. But even if fertility ceases to decline below its present level we are faced with a declining population in the near future, and with a population that some believe will deteriorate in quality as well as quantity, through the effects of differential fertility.

As BLACKER and GLASS admit, many good arguments can be urged for preferring a stationary or a slowly growing population to a rapidly expanding one, but a declining population is quite another matter. Only an increased fertility can avert it. Is that a likely event? Are there any means of encouraging it? Unless we know the reasons for the falling birth rate we clearly can take no steps to arrest its decline. In the second section of their pamphlet BLACKER and GLASS devote themselves to this subject. Sterility they think is not increasing and they lay more stress on social and economic reasons—the difficulty of parents supporting more than a small number of children, of finding them suitable employment as they reach maturity, of giving them and themselves the social advantages, comforts, and standards of life that they desire. Under psychological reasons they refer to the parental instinct that is satisfied by one or two children—"when parenthood is being increasingly planned, the strength of the desire for children as measured by the number of children by which it can be adequately satisfied, comes into an entirely new prominence as a biological factor to which is attached the clearest survival value." The uncertain political and social condition of the world must also play its part. Fertility cannot be raised, they conclude, unless there is a change of attitude of the kind they call "psychological" about the family, unless people can somehow be inspired to want children. McCLEARY is much of the same mind. Though he is satisfied that economic factors are at work, he thinks that the really important causes of depopulation lie deeper in the conditions of modern life. "If babies are not to be had for love they are not likely to be had for money." Certainly the efforts by the latter means taken in Germany and Italy have been attended by no striking success,⁵ though the economic incentives offered may well have been

too small. But if effective action is to be taken we must know more of the possible factors that are thought to influence people in restricting their families. This problem the Population Investigation Committee hopes to investigate, and an appeal is made for funds to enable it to do so. There are two lines it wishes to follow—namely statistical analysis and direct inquiry. Under the first, calculation may be made of the extent to which people living in different regions, urban and rural, and working in different industries and occupations, are replacing themselves. Under the latter, by questionnaire, further light may be thrown on differential fertility, on medical causes of infertility, on the degree of success attending contraception, on the effects of uncertainty of employment, on the "psychological" factors involved. Perhaps, as some have argued, there is a law of population growth or there are, as BROWNLEE believed, changes in germinal vitality that we cannot influence. Perhaps, as others believe, "the innumerable distractions of modern life are far more tempting to the average man and woman than is the bringing up of children," the only remedy for which is the "reawakening of the race as a whole to its responsibilities as a civilising factor."⁶ The problem is exceedingly complex, but of vital national importance if "western civilisation is not to go the way of Greece and Rome to decay and death." That fear some may think unduly alarmist, but the pamphlet under review shows clearly the experts' reasons for disquiet. It gives no one an excuse for remaining ignorant of the situation.

NEW METHODS OF IMMUNISATION AGAINST DIPHTHERIA

To protect a particular child against diphtheria is comparatively easy: there is a wide choice of immunising agents and methods which are all reasonably satisfactory for the purpose. To protect a community is far less simple, since the method adopted must be uniform, must give as complete and lasting protection as possible, must not produce serious reactions, and must be cheap and manageable. The dilemma is well known and no way of circumventing it has been found. The difficulty is that, on the one hand, a single injection either fails to give immunity in a satisfactory proportion of cases or causes too severe reactions, while on the other hand, mothers do not like to bring their children for a series of injections, particularly if these have to be repeated at intervals in order to keep the antitoxin at a suitable level.

A possible way out was demonstrated by Prof. CLAUS JENSEN, director of the department of biological standards at the State Serum Institute of Copenhagen, in a paper given to the epidemiological section of the Royal Society of Medicine on April 9th. The method he adopts, which is supported by many years' work and much experiment, is a single subcutaneous injection of Schmidt's

⁶ *Daily Telegraph*, April 6th, 1937.

purified aluminium hydroxide toxoid followed by intranasal instillations of purified toxoid dilution. His conclusions are based entirely on quantitative estimations of antitoxin which clearly afford more accurate information than for example skin reactions. Various series of rabbits, children and adults first had their natural antitoxin quantitatively determined and then were divided into four groups according to the amount of circulating antitoxin—i.e. less than 0.0005, less than 0.01, less than 0.10 and more than 0.10 antitoxin unit per c.c.m. Four weeks after the single injection of purified $Al(OH)_3$ -toxoid the groups were redetermined and this was done again after 6 or 3 nasal instillations at stated intervals. The results were ingeniously shown by what Dr JENSEN calls antitoxin spectra—i.e. coloured histograms resembling the appearances seen in spectroscopy. In all three groups (rabbits, children and adults) the results appeared to be excellent: the effect of the intranasal instillations being greatest in those who gave a poor response to the subcutaneous injection. There were no reactions to the nasal instillations in children but in adults (probationer nurses) transitory headache, nausea or fatigue were occasionally experienced. Of the children 100 per cent developed more than 0.01 unit of antitoxin six weeks later and 96 to 100 per cent developed 0.10 unit or more. Nine months afterwards the immunity appeared to have fallen off considerably but the response to nasal reimmunisation only after twelve months was even better than to the original combined treatment. In the group of 319 probationer nurses 94 per cent developed more than 0.01 unit and 85 per cent more than 0.10 unit while 1 per cent were refractory. Dr JENSEN is sufficiently convinced of the value of his method to recommend its adoption for all children without preliminary or control Schick testing. Mass immunisation of the child population against diphtheria has not been attempted in Denmark hitherto; the experiments recorded being confined to schools and institutions. This is partly owing to the rarity of epidemics of diphtheria in Denmark and partly to deliberate abstention until the most efficient and practical method had been determined. But diphtheria is prevalent in many of the surrounding countries and the proportion of natural immunes in the child population is low—far lower than in England for example—and the danger is therefore considerable. Dr JENSEN hopes that the Department of Health will now start a drive for immunisation and thinks that by efficient propaganda nearly the whole of the children of Denmark—some 700,000—might be immunised by his method within about a year and the immunity kept up by repeated annual intranasal instillations.

In sum several definite advantages may be claimed for JENSEN'S method and since pre-sent methods are not entirely satisfactory, bacteriologists and public health authorities should examine his claims with care. Whether in England it would be thought advisable to entrust the intranasal instillation to the mothers is doubtful; perhaps the health visitor would be a more suitable

agent. But anything which smooths the path between academic and practical immunology is welcome and the careful work done in Denmark as well as its attractive presentation demands serious attention.

THE MEDICINE DUTIES AND THE CHEMIST

THE Select Committee on the Medicine Stamp Duties was somewhat ruthless in its recommendations. It was natural that its report should display impatience at the continued retention on the statute book of legislation like the Medicines Stamp Act of 1812 with its list which begins with Adam's Solvent, Addison's Re-animating European Balm and Aethereal Anodyne Spirit and ends with York Medicinal Preventive Lotion and Zimmerman's Stimulating Fluid. The committee of course was concerned with the revenue aspect not with pharmacology and it is reasonable to suppose that the CHANCELLOR OF THE EXCHEQUER will take no step in his forthcoming Budget without careful consultation with the interests specially affected. Strong protests are meanwhile being made against the proposals in the committee's report. The recommendation that with a few exceptions all drugs and medicaments, herbs, disinfectants and soaps should be made liable to a duty based on the retail selling price is a proposal for a novel and irritating form of sales tax. It is urged that the State should not single out for taxation those medicinal substances which are used by persons in ill health. The weapon of taxation it is said will be employed to discourage a proper statement upon labels and accompanying literature of the conditions in which a medicine is to be taken. Manufacturers will cease to have any inducement to disclose in their labels the composition of their medicaments with the result that we shall return to the abuse of secret remedies. Prescribing over the counter would be embarrassed; the last surviving privilege of the pharmaceutical profession, the chemist's right to prescribe and sell his own medicine to his customers without having to stamp it, would disappear. The consultative value of his training would be belittled. If the customers ask for an ounce of castor oil they will get it at the normal price of so much oleum ricini. But if they ask him to suggest an aperient or if they mention castor oil and ask his advice about the dose, he will have to affix a stamp and pay the duty.

The general position of the registered pharmacist seems to be threatened by the committee's report. It observes that the Act of 1783 was intended to tax the quack and to exempt those bred to the profession of physician or apothecary. But observes the committee, qualified chemists have in effect obtained the privilege of selling the bulk of their ready-made preparations duty free while precisely the same preparations if sold by a grocer must pay duty. The committee seems to doubt the benefit of specialised pharmaceutical training. Is there no safeguard to the public in the presence of a registered pharmacist on premises where medicines are sold? The committee apparently

thinks this protection is illusory—at any rate on premises where there are large sales of ready-packed medicines. It may be doubted if Parliament or the public would share this very depreciatory opinion.

IMPROVEMENT OF POSTURE

Mr PHILIP WILES has chosen a good moment for presenting his views on postural deformities—the subject of his Hunterian lecture published in our present issue. At a time when much is being said about the need for improved physique and the Government is prepared to spend money to this end, the nation, like other sick persons, may suffer from contradictory advice. It is therefore important, wherever possible, to collect information that will fill the gaps in our knowledge, so that there may be no doubt as to what are the fundamentals of physical efficiency and the methods by which they may be attained. When “physical training” is going to be made available for every child and adult in the country, it is necessary for example that zealous organisers should not remain ignorant of the dangers of haphazard application of gymnastic exercises to anyone and everyone. Physical exercises, as LEDENT¹ puts it, should be regarded as a drug, and no drug has equally beneficial effects on all patients at all times and in the same dose.

In his lecture Mr WILES brings together facts gathered during many years by many workers, both here and abroad. To these he adds observations he has made with an ingenious gauge for measuring the pelvic tilt. These observations, though few in relation to such surveys as that made by the Board of Education in 1935, will be found very interesting. He rightly points out that as the pelvis is the base of the spine, its axis has a fundamental effect on the attitude of the parts above. The question is whether he does not pass rather too lightly over the influence of the parts below—the knees and feet for example, which form the actual pedestal for the human machine. Although he accepts as correct GOLDTHWAIT'S straight axis for the human body, passing through mastoid, shoulder, hip, front of knee, and ankle, his photographs of “normal” persons would not coincide with GOLDTHWAIT'S satisfactory posture. In regard to posture, more perhaps than anywhere else in medicine, it is difficult to get any two practitioners to agree to the same definition of “normal” and “efficient.” Our ideal for the human race is by no means synonymous with survival value in evolution. The biologist points out that the amoeba has survived from primeval times and is biologically as efficient as the most brilliant scientist. Physical strength does not necessarily imply strength against disease, and on the other hand the weedy slum dweller, with his comparative efficiency in the war against bacteria, might easily be bowled over by an overdose of “physical training.” Though Mr

WILES refers to it, he does not perhaps put quite enough emphasis on the necessity of balancing the prescription of exercise with a correspondingly weighty dose of rest. This is implied however in his insistence that posture is a function of the central nervous system as a whole, and that its improvement depends on the patient's coöperation and on the restoration of a series of reflexes whose pattern has been disturbed by such disorders as rapid growth, toxæmia, or anxiety. The emotional factors influencing posture can scarcely be exaggerated, but if we were to argue too closely from the physical to the mental, the sight of any gathering of ordinary people—even a medical audience—would bring despair for the intellectual prospects of Britain!

Not all will agree with Mr WILES in making light of the influence on growing tissues of such external factors as violins and school desks. HUNTER demonstrated the plasticity of adult bones in response to the strains of various trades. He is on firmer ground in condemning attempts to “stretch” muscles and ligaments by force, since it is now recognised that muscles can only be lengthened satisfactorily by encouraging their reflex relaxation, as their antagonists contract, while ligaments yield best to persistent traction in their long axis. It should not be forgotten that lying on the ground provides just that resistance to the flexors, and support for the extensors, which Mr WILES recommends as the basis of exercises for correction of posture.

BRUCELLA MELITENSIS IN THE UNITED STATES

EXCEPT in the hog raising district of the middle west, where infections with *Brucella suis* are common, undulant fever in the United States is nearly always due to *Br. abortus* which comes directly or indirectly from the cow. *Br. melitensis* infections have so far been restricted to the south western States where some goat's milk is drunk. From a survey by Miss Alice C. Evans,¹ of the National Institute of Health it seems possible that infections with the *melitensis* type may be rather commoner than has been apparent, and that infection may sometimes be distributed by cow's milk. Using the quantitative absorption technique she examined sera from 27 patients having a titre of 1/160 or over. The results suggested that 14 were infected with the *abortus* and 13 with the *melitensis* type. Of the patients in the latter group 5 lived in North Carolina and 6 in Texas—both States in which goats are few. It is doubtful however whether this justifies the conclusion that these patients must have been infected from cattle. That cattle may be infected with *Br. melitensis*, and that human beings may contract undulant fever from cow's milk containing this organism, has been amply demonstrated by Taylor and his colleagues at Montpellier. But the evidence contained in Miss Evans's present paper is only circumstantial. Cows have never been found to be infected with the *melitensis* type except when running with goats, and the risk of their being infected in areas free from goats seems slight. In this country indigenous *melitensis* infection has never been satisfactorily demonstrated.

ANNOTATIONS

AN INTERNATIONAL ASSOCIATION OF THE MEDICAL PRESS

A MOVEMENT was projected from Milan last summer for the organisation of an International Association of the Medical Press and the preliminary statement was to the effect that the first president would be Dr Hans Spatz the editor of the *Munchener Medizinische Wochenschrift* the first treasurer Dr Benno Schwabe and the secretary general Signor Santo Vansias giving his address as Ca della postale 3395 Milan. Among the council the names were printed without any previous sanction of the editor of *The Lancet* and the editor of the *Journal of the American Medical Association* together with the editors of a dozen or fifteen other medical journals who may or may not have given permission. The editor of *The Lancet* not being satisfied that anything practical at the present stage of European politics could develop from the movement asked that his name and that of *The Lancet* placed on the circular without approval having been asked should be removed. Dr Fishbein, editor of the *Journal of the American Medical Association* being communicated with said that his name and that of his journal also appeared on the circulars without any authority and he enclosed to us a copy of a letter in which he had protested against the treatment he had received. Dr Fishbein was more fortunate than the editor of *The Lancet*, for he obtained a courteous statement from Signor Santo Vansias the source of all the communications in the following words: "I was merely showing the basis for my future work in case of acceptance. According to your wishes I cancel my previous indications although I have confidence that your ideals agree with mine. The editor of *The Lancet* not only received no assurance that the references to the paper and to himself would be cancelled but finds that his name and that of *The Lancet* still remain on the circulars. In the last circular received the name of Dr Hans Spatz is still given as president of the projected Association and that of Dr Benno Schwabe as treasurer. We have now received a communication from Dr Hans Spatz that his name has been used without his authority and that, in spite of repeated protests it has until now not been expunged from the lists. He adds also that false announcements of his appointment as president have been made in the German daily press. Further Dr Spatz has been informed by Dr Benno Schwabe that the printed statements of his position as treasurer to the movement have been made without his consent. Dr Hans Spatz has published in the German press the withdrawal of his name from the Association with a criticism of the extraordinary procedures of the secretary general. In publishing this repudiation by *The Lancet* of any connexion with the movement, we are asked by Dr Spatz to associate his name with our protest."

DEFICIENCIES IN ULCERATIVE COLITIS

ONE of the most interesting aspects of biological processes is the way in which a specific effect however brought about always tends to set up the same train of events. If a number of causes bring about the specific effect the resulting train of events may be common to a number of conditions although modified and supplemented in each of them by the particular exciting cause. The appreciation of these syndromes which are common to a number of diseases

is of enormous importance in theoretical medicine although practical medicine—the slave of diagnosis—depends more upon the recognition of the particular response. The rise of body temperature (and its inevitable sequelae) which accompanies many toxic processes is a good example of a general response that may be produced by many different stimuli. Another example is salt deficiency which is common to Addison's disease, pyloric stenosis, excessive sweating, diarrhoea and vomiting and (according to Welch, Adams and Wakefield¹ of the Mayo Clinic) ulcerative colitis. A third example less often recognised is the response of the body to a forced and continuous loss of protein material. Such losses are met with in for example pregnancy, lactation, chronic parenchymatous nephritis and (as is also demonstrated by Welch and his colleagues) ulcerative colitis. In all of these conditions the blood urea tends to be low indicating a small catabolism of amino acids and suggesting that all the available ones are being used for the synthesis of the protein which is being lost: the urea nitrogen in consequence forms very much less than the normal 70–80 per cent. of the total nitrogen leaving the body. Where this happens it is clear that the treatment should include high protein feeding and while the success of a generous protein intake in chronic parenchymatous nephritis is well known and the value of protein in pregnancy and lactation is also accepted the Mayo Clinic workers do well to point out the necessity for a liberal protein diet in ulcerative colitis.

FLUORINE POISONING

MANY of our readers will recall the fog disaster which occurred² in the valley of the Meuse above Liège early in December 1930. Within a few days several thousands persons suffered from an acute pulmonary affection and 60 lost their lives. A commission of inquiry was set up which came to the conclusion that the disaster was due to the accumulation of waste factory products in the air of the narrow steep river valley, a blanket of cold fog during windless weather acting like a closed roof to the valley. The commission suggested that sulphur dioxide (or its derivatives) was the chemical substance responsible. Those who were familiar with the physiological effects of SO₂, and especially those who have experienced considerable or prolonged exposure to this gas were not impressed by the findings of the commission on this head. Dr Kaj Roholm of Copenhagen now surveys³ the whole problem in the light of more recent knowledge about the toxicity of fluorine and its compounds⁴ and makes out a strong case for the belief that fluorine and not sulphur was the peccant agent. Here was a narrow deep valley, a dense pall of almost stationary fog and in two places in the valley (at Engis and in the Sclousin Serrain area) a number of factories (15 in all) throwing considerable quantities of fluorine into the air. It may be unlikely that such a combination of circumstances will arise in this country but the possibility that chronic fluorine poisoning may be occurring cannot be so easily dismissed.

Fluorine poisoning may be produced as a result of industrial processes, from the ingestion of fluorine

¹ Welch, C. H., Adams, M., and Wakefield, F. C. *J. Clin. Invest.* 1935, 14, 161.

² *See Lancet*, 1930, 2, 1203.

³ A paper read before the Danish Society for Internal Medicine, *J. Intern. Med.*, March 1937, 2, 1.

contaminated soil or water, or occasionally (as in Iceland) it may arise from the dust of volcanic eruptions after it has settled on the soil. A number of industrial processes make use of raw materials containing fluorides: (1) Blast furnaces, steel and metal works. Dr Roholm estimates the world's yearly output of calcium fluoride (fluorspar CaF_2) at 200,000–300,000 tons of which 80 per cent is used in blast furnaces. During the smelting of iron and steel, silicon tetrafluoride escapes into the air. (2) Glass and ceramic manufacture. (3) Zinc smelting. Zinc ore usually contains fluorspar. (4) Superphosphate manufacture. Phosphatite contains fluoride. (5) Chemical works. In the neighbourhood of some of the factories in the Meuse valley, it was observed that glass rapidly lost some of its transparency. Plant life was damaged around some of the factories. Animals fed upon contaminated herbage suffered from dental and bone diseases or died with emaciation and cachexia.

In acute fluorine poisoning resulting from breathing contaminated air, the symptoms and signs are those of an acute pulmonary oedema, similar to that seen after exposure to certain "poison gases." In chronic poisoning (whether the "fluorine" is air or water-borne), the characteristic symptoms are mottling of the enamel of the teeth, bony changes, (a) either a diffuse osteo sclerosis with deposits in the ligamentous insertions of the muscles, or (b) bony degeneration and softening (when the poisoning is more severe), general wasting, anaemia and cachexia. Now that attention has been drawn to this matter, no doubt a careful study of the possible risk in our industrial areas will be made. Dr Roholm insists that factories giving off fluorine compounds should be required to take measures for effective removal of the fluorine compounds from chimney smoke.

CAROTID SINUS FAINTING ATTACKS

If medical problems often stimulate physiological research, physiological discoveries often point the way to advances in medicine. The latter sequence is exemplified by the story of the carotid sinus. In the last ten years the physiologists, led by Hering and Heymans, have elucidated the function of this curious bulbous dilatation at the origin of the internal carotid artery, the walls of which, as well as the substance of the adjacent highly vascular carotid body, are furnished with numerous afferent nerve endings. These endings are stimulated by the mechanical stretching of the sinus walls due to the pressure of its contained blood, and also (probably those in the carotid body) by certain chemical changes in the blood, such as carbon dioxide excess, oxygen deficit, and the presence of sodium cyanide in minute amounts. Nerve impulses from the stimulated endings ascend in the vagus and glossopharyngeal nerves to the medulla and give rise to certain well defined reflex effects notably slowing of the heart, splanchnic vasodilatation with fall in blood pressure, and increased breathing. In respect of blood pressure, the carotid sinus mechanism clearly supplements the earlier known depressor reflex from the aortic wall in counteracting excessive rise in aortic pressure and thereby regulating the general blood pressure and the blood supply to the brain. As to respiration, some of the effects formerly attributed to the action on the respiratory centre of changes in the amount or composition of its blood supply are now seen to be brought about by the carotid sinus mechanism.

Soma Weiss and his colleagues have lately looked to the carotid sinus as an explanation of some varieties

of fainting attack in man, and they summarise their observations of the last few years in a recent paper.¹ If the patient's fainting attack can be reproduced at will by digital pressure over his carotid sinus in the neck, they argue that a hypersensitiveness of the reflex is the mechanism of the attack, the conclusion is supported by other evidence as well. They have investigated 57 patients showing this phenomenon, and they remark incidentally that many of them showed local anatomical lesions, such as tuberculous adenitis of glands near the carotid bifurcation, or athero sclerotic lesions in the vessel itself. The induced fainting attacks fall into three groups. In the first a vagal effect predominated, with slowing or transient stoppage of the heart, which could be prevented by atropine. In the second, splanchnic dilatation and fall of blood pressure occurred, indicating a release of sympathetic vasoconstrictor tone as the chief reflex effect, adrenaline counteracted this, while small doses of nitrites accentuated it. In the third group carotid sinus stimulation apparently produced curious faints, with features suggesting amnesia, sleep, or cataplexy, which are more difficult to explain physiologically, since blood pressure and heart rate were unaltered. The authors note that the patients subject to carotid sinus attacks often show evidence of what they call vegetative neuroses—"functional" symptoms such as constant fatigue, mental depression, palpitation, emotional instability. They could offer little evidence, however, that the carotid sinus was responsible for any symptoms other than the fainting attacks and phenomena directly associated with them. In 8 of 10 cases in which the carotid sinuses were surgically denervated, the syncopal attacks ceased but the other features remained unaltered. The authors conclude therefore that they have displayed a reflex physiological mechanism for a symptom hitherto classed as "functional" and often "neurotic," and they wonder how many more disorders of the same class, in the behaviour of the autonomic nervous system, may be amenable to similar explanation.

A SOUTH AFRICAN PROPRIETARY MEDICINES BILL

A Proprietary Medicines and Appliances Bill has been introduced into the South African Parliament which may have far reaching results. It would make it an offence to print, publish, or distribute an advertisement of a proprietary article which is indecent or improper, or fails to state the manufacturer's name and address, or refers to a testimonial, or offers free treatment, or states that the article is a cure for any disease. The Bill goes further indeed, than similar proposed legislation elsewhere, for it would penalise the use in advertisements of the words "professor," "doctor," "physician," or "surgeon." It forbids too any such advertisement which is "likely to conjure up in the mind of a reasonable man the fear of serious consequences from some trivial complaint." Finally, the advertisement must not by name or implication refer to certain diseases scheduled as incurable or requiring special treatment. There is an exception for appliances for deafness or rupture, but the list in the schedule includes alcoholism, appendicitis, blindness, cancer, deafness, diabetes, high blood pressure, infantile paralysis, malaria, pneumonia, sexual impotence, tuberculosis, and venereal diseases. If the Bill were

¹ Ferris E B, Jr, Capps R B, and Weiss S, *Arch. Neurol. Psych.* February 1937, p. 365.

to be passed into law it would of course affect British newspapers introduced into South Africa which contain forbidden advertisements of this kind. Even if it does not become law in its proposed form, the Bill will have offered opportunity for useful discussion and will give newspaper proprietors material for considering the imposition of voluntary standards.

ERADICATION OF TSETSE FROM RIVER AREAS

THE Colonial Development Fund has lately financed an interesting experiment in Kenya. By the expenditure of some £2400 an area of 4000 acres of highly fertile land which had been derelict for thirty years owing to sleeping-sickness has been rendered safe for habitation. An account of the measures adopted has been written by Mr C. B. Symes, medical entomologist and Mr R. T. Vane, tsetse field assistant.¹

The great epidemic of sleeping-sickness which decimated Uganda between 1901 and 1908 spread to the eastern shores of the Victoria Nyansa, and the disease is still endemic on the coast and particularly in the Kaji river basin. Kaniadoto a district in this area was chosen for the experiment because surveys had shown a high incidence of trypanosomiasis. The dense bush along the river and its tributaries is infested with *Glossina palpalis* and the population has been driven to the higher ground which is largely waterless and destitute of trees. These conditions have compelled the people to go down to the streams for water and wood and to water their herds and in doing so they could not avoid contact with the heavily infested bush which varies from 100 yards to a mile in width. The essential feature of the experiment was a piecemeal attack on the bush, the trees are chiefly acacia and thorn but there is a mass of undergrowth and creepers. Five clearings were made varying in width from 500 to 1050 yards at the sites of the most used watering places and fords. When the heavier vegetation had been burned out the undergrowth and creepers were hacked down by gangs of natives. As soon as the five clearings had been made the attack was directed to the blocks of bush which had been left. These were systematically cleared of fly by the use of Swinnerton's screen traps which were most efficient when the fly-density was high. In the later stages great and rapid progress was made by hand catching with nets. The efficiency of these measures may be judged by the fact that in one block nearly 40 000 tsetse were captured. The glossina is big enough to be marked and at different times, some thousands of specimens, rendered identifiable by spots of oil-colour were set free. Their recapture determined how far the clearings were effective and it was noted that few flies managed to cross a cleared area 1000 yards wide. Other interesting details of the habits of the tsetse were also obtained; for example it was found to be more active and more prolific during wet seasons. Among the labour force which comprised an average of 90 natives, 5 cases of trypanosomiasis were recognised but the men were immediately removed and treated and are now well.

The net result of the experiment is that eleven miles of river have been cleared of bush and six square miles of highly fertile land have been rendered available for occupation. In June 1935 400 men

women and children (93 families) were settled on the area, most of which is now under cultivation. Another three square miles have been cleared but will not be safe until an extension has been made. Provided that cultivation is maintained the cost of keeping the cleared area clean will not exceed £75 per annum. A complete scheme for this district would probably require another six to eight years work. Unfortunately the block method is not applicable to the coastal districts and until some measure be devised for dealing with them we cannot expect a return of the prosperous conditions which obtained in this part of the Nyanza province before it was attacked by the trypanosome.

SPEECH THERAPY

FORTUNATELY most of us learn to speak without effort, or at least the effort is not remembered. The vocal apparatus and its use are so complicated however that imperfect speech once acquired is difficult to correct, especially as the patients are most commonly either very young children or over-anxious adults. The mental energy required to study the physiology of speech is greater than most medical students have to spare and as far as doctors are concerned the subject has largely remained a mystery enshrined in very specialised clinics. Two monographs recently issued throw light on different aspects of the work of speech therapy. Miss Parsons writes charmingly.¹ The illustrated story of Mr Tongue's walks to the houses of Mr Soft Palate and Mr Teeth and his meetings with the Diphthong boys provides one example among many of how speech exercises for the young child may be made entertaining. The scientific part of the book is intentionally slight. The book is obviously written by a born teacher and can be recommended not only to doctors who want to know the sort of thing speech therapists do (or could do) but to parents of children with speech defects. Miss McAllister's book² is a more weighty contribution to speech therapy and will arouse more controversy. The two divisions of the book deal with stammering and with stuttering, the terms being used in very wide senses. For example all defects of articulation are classified under the heading stammering even if these arise only on account of defective hearing. The descriptions of such cases suggest some confusion in the author's mind between the intensity and the pitch of sounds, and in respect of other physical factors in the problem. Experienced teachers of the deaf would certainly and rightly object to children with grossly defective hearing being left in a speech therapy clinic instead of being sent to a school for the deaf. Miss McAllister quotes statistics showing that 5.0 per cent of 21 452 children in Dunbartonshire suffer from some kind of speech disability and suggests that the incidence is similar elsewhere. On this account she pleads for a trained speech therapist on the staff of every school with over 400 children believing that occasional attendance at a clinic is unsatisfactory. Another written contribution³ to the popularisation of speech therapy has recently come from Mr H. St. John Ramsey who has corrected himself of stammering and has had 15 years of experience in treating other people. He

discusses the subject clearly and concisely, and his little book is particularly suitable for intelligent adult patients

ENCEPHALITIS IN JAPAN

THERE was an epidemic of encephalitis in Japan in 1873 and another in 1911. The latter was looked on as a cerebro spinal meningitis, and it was not until the epidemic of 1924, in which over 6000 cases were reported, that the true nature of the 1911 outbreak was realised. In 1929 there was a smaller outbreak, with nearly 2000 cases, and the disease was prevalent again in 1935 (5000 cases). Apparently it is more or less endemic in Japan, at any rate in the summer months, especially in certain seaside places. In 1933 a committee was appointed to investigate it, and as head of this committee Inada is now reviewing its work in a French journal.¹ Real progress as regards the aetiology of the disease dates, he says, only from 1933, when Hayashi succeeded in transmitting it to Java monkeys. In the same year besides transmitting encephalitis to monkeys Webster and Fite in the United States succeeded in infecting mice. This opened up wide possibilities, which the committee fully used in the 1935 epidemic. They find that up to the seventh day of disease inoculations of brain matter will usually infect mice. It has also been possible to infect them with blood, either directly inoculated or transmitted through mosquitoes. Cerebro spinal fluid was most infective for mice during the second to fifth days of disease. It was noted that virulence sometimes increased after the third or fourth passage through the mouse. Monkeys, it now appears, are less susceptible than mice, and their susceptibility varies with species and age. The incubation period when human material is directly inoculated into the monkey appears to be about 5-8 days. As regards mode of infection, Inada considers two hypotheses— infection through the nasal mucosa and infection by the bite of an infected mosquito. In weighing these it must not be forgotten that the Japanese epidemic and the St. Louis epidemic—with both of which these observations deal—differed in several ways from the great European epidemics of 1917-26. In particular, the difference in the season at which they occurred has a bearing on the mode of spread. The outbreaks in the European (lethargic) epidemics were almost limited to the colder months, their recurrent peaks were in the second half of the winter, the Japanese and St. Louis outbreaks, on the other hand, were in the summer. The idea that the disease is transmitted through the nose is based on the fact that typical changes have been found in the brain after direct nasal infection of animals, and the finding of the virus in nasal washings, the difficulty of accepting it is the rarity of multiple cases of infection in one household. All the Japanese workers agree that in animals infection by the nose is more often successful than subcutaneous or intracranial injection and indeed is only second to direct cerebral inoculation. Twenty-four hours after nasal injection into the mouse the virus can be obtained from the olfactory lobe and transmitted with it to another animal. Infection by mosquito bites have been unsuccessfully attempted in the United States, but has been achieved in Japan with difficulty and after repeated passages. It seems evident that certain forms of mosquito can harbour the virus, but further observations are necessary before one can decide how far this fact affects mankind.

CHOLINE DERIVATIVES

NOT long ago¹ we referred to the modern tendency to search among substances chemically related to powerful drugs and hormones in the hope of discovering compounds in which a single activity of the parent substance is prominently exhibited, and by way of example we cited the action of carbaminoylcholine on the bladder in certain cases of retention of urine. A valuable account of the effect of this drug on 26 normal persons has since been given by Prof. Starr² of Philadelphia, and includes a record of his own experience after taking a large dose. A similar investigation by Myerson, Loman, and Dameshek³ of Boston has been made for acetyl beta methylcholine (Mecholyl), and a comparison of the effects of the two substances is interesting. They are both parasympathomimetic, acting on the circulatory system, the alimentary tract, bladder, and skin. The effect of mecholyl is prompt, marked, and transient, and includes flushing of the face and chest, perspiration, salivation, rhinorrhœa, lacrymation, fall of blood pressure, and an increased pulse rate which the authors are at a loss to explain. Carbaminoylcholine (Doryl) is slower but more prolonged in its action which is otherwise similar in many respects to that of mecholyl. Prominent among the symptoms to which it gives rise are, however, increased peristalsis and colic, and although flushing and sweating are conspicuous, the effects on pulse and blood pressure are slight. With both drugs atropine annuls unpleasant effects, though animal experiments show that carbaminoylcholine has a stronger "nicotine action" than mecholyl and the consequent stimulation of autonomic ganglia must persist even after atropine. The action of mecholyl on the alimentary tract is slight, but more work is necessary before it can be assumed with confidence that this is the drug of choice for circulatory effects and carbaminoylcholine for visceral activity. The length of time for which the substances act introduces a complicating factor. Thus Kramer⁴ of Philadelphia reports good results in peripheral vascular diseases using mecholyl, but finds difficulty with thrombo angustis obliterans. Starr, on the other hand, records two cases of thrombo angustis obliterans which benefited greatly from carbaminoylcholine, the reason being, apparently, the more prolonged action of this drug. The American investigators seem primarily interested in the relief of peripheral vascular lesions, and their results are on the whole encouraging. They point out the danger of treating patients with a tendency to asthma with choline derivatives, and although atropine is effective in preventing disastrous effects, such patients are not likely to benefit from the more desirable peripheral actions of the drugs.

Summer Time will commence in Great Britain, Ireland, the Channel Islands, and the Isle of Man on Sunday morning next, April 18th, at 2 A.M., when the hands of timepieces should be advanced one hour. It will end on Sunday, Oct. 3rd. Summer time began in France on Saturday, April 3rd, at 11 P.M., and will end there at midnight on Saturday, Oct. 2nd.

PRINCIPLES OF MEDICAL STATISTICS

XVI.—CALCULATION OF THE STANDARD DEVIATION *

In Table III which appeared in the article on the variability of observations and is here reprinted there are given twenty observations of systolic blood pressure of which the mean value was found to be 128. The variability of these observations was measured by means of the standard deviation

TABLE III

(Reprinted from THE LANCET Jan. 23rd 1937 p. 219)

Twenty observations of systolic blood pressure.	Deviation of each observation from the mean (mean = 128)	Square of each deviation from the mean.
(1)	(2)	(3)
98	-30	900
100	-28	784
136	+8	64
108	+10	100
130	+2	4
114	-14	196
125	-3	9
134	+6	36
128	0	0
107	-21	441
123	-5	25
135	+7	49
109	+1	1
132	+4	16
104	-20	400
115	-13	169
120	-8	64
132	+4	16
130	+2	4
Sum 2600	0	3674

This value was calculated by (1) finding by how much each observation differed from the mean (2) squaring each of those differences (3) adding up these squares and finding their mean by dividing by the number of observations (4) taking the square root of this number. Putting this in symbols if the number of observations is n each observation is designated by x and the mean of them by $\bar{x}$ then the standard deviation equals

$$\sqrt{\frac{\text{Sum of values of } (x - \bar{x})^2}{n}}$$

This method of calculation would have been much more laborious if the mean blood pressure had not been a whole number—e.g. if it had been 128.4—and if each of the original observations had been taken to one decimal place—e.g. the first had been 98.7. The differences between the observations and their mean and the squares of these values would then have been less simple to calculate. But in such cases the necessary arithmetic can still be kept simple by a slight change of method.

The Ungrouped Series

Instead of measuring the differences between the observations and their mean we can first take those differences from some other point any point which makes the calculation simpler and make a correction at the end for having done so. For instance taking the figures of Table III instead of calculating the differences between the observations and their mean

In accordance with many requests I am adding to this series of which the main argument was concluded in THE LANCET of last week two additional articles on the calculation of (1) the standard deviation and (2) the correlation coefficient. The latter will appear next week.

value 128 let us measure the differences between the observations and 100. These differences are given in column (2) of Table III A and their squares in column (3). The sum of the squared deviations from 100 is 19354 and the mean squared difference is therefore $19354 \div 20 = 967.7$. To this value we must now make a correction for having measured the deviations from 100 instead of from the mean of 128. The correction is to subtract from this mean square value of 967.7 the square of the distance between the value from which we chose to measure the deviations (100 in this case) and the value from which we ought to have measured them (128). Thus we have 967.7 minus $(128-100)^2$ or $(28)^2 = 784$ which gives 183.7. The standard deviation is then $\sqrt{183.7} = 13.56$ the value we reached before by taking the deviations from the mean itself.

TABLE III A

Calculation of Standard Deviation Ungrouped Series

Twenty observations of systolic blood pressure.	Deviation of each observation from 100	(Deviation) ²	Square of observation
(1)	(2)	(3)	(4)
98	-2	4	9604
100	+0	0	10000
136	+36	1296	18496
108	+8	64	11664
130	+30	900	16900
114	+14	196	12996
125	+25	625	15625
134	+34	1156	17956
128	+28	784	16384
107	-7	49	11449
123	+23	529	15129
135	+35	1225	18225
109	+9	81	11881
132	+32	1024	17424
104	-4	16	10816
115	+15	225	13225
120	+20	400	14400
132	+32	1024	17424
130	+30	900	16900
Sum 2560	—	19354	331354

If the observations all lie near one hundred this is a convenient method of working for the deviations are thus reduced to a size which is easy to handle and the squares can often be done in one's head. On the other hand one has to make subtractions from 100 to obtain the deviations. Even this step can be eliminated by measuring the deviations of the observations from zero—i.e. by squaring the observations themselves as is done in column (4). The squares can be taken from a book of tables (e.g. Barlow's Tables of Squares Cubes Square Roots &c. London E. and F. Spon 1930 7s. 6d.).

This obviates finding any deviations at all.

The sum of these squares is 331354 and the mean square is $331354 \div 20 = 16567.7$. In using the squares of the observations themselves we have measured their deviations from 0 instead of from the mean value of 128. Therefore the distance between the value from which we chose to measure the deviations and the value from which we ought to have measured them is 128. As correction we must then subtract $(128)^2$ from our mean square value. This gives 16567.7 minus $16384 = 183.7$ and the standard deviation is $\sqrt{183.7} = 13.56$ as before. To calculate the standard deviation in a short ungrouped series of figures the procedure is then as follows: (1) find the mean of the observations (2) square each

observation, (3) sum these squares and find their mean, (4) from this mean square subtract the square of the mean, (5) the square root of this last value is the standard deviation

The standard deviation therefore equals —

$$\sqrt{\frac{\text{sum of squares of observations}}{\text{number of observations}} - (\text{mean of observations})^2}$$

or in symbols is $\sqrt{\frac{\text{sum of } (x)^2}{n} - (\bar{x})^2}$

(The proof of the correction is quite simple but the worker who wishes to apply the method has no need to worry about it)

The Grouped Series

With a large number of observations this method of squaring each observation would be very laborious. A shorter method which will give very nearly the same result can be adopted. The observations must first be grouped in a frequency distribution. As an example we may take the distribution given in Table II (see *Lancet*, Jan 23rd, p 219) of the ages at death from diseases of the Fallopian tube. This distribution is given again in column (2) of Table III B.

TABLE III B

Calculation of Standard Deviation Grouped Series

Age in years	Number of deaths in each age group	Age in working units	(2) × (3)	(3) × (4)
(1)	(2)	(3)	(4)	(5)
0—	1	-5	-5	36
5—	—	-5	—	—
10—	1	-4	-4	16
15—	7	-3	-21	63
20—	12	-2	-24	48
25—	35	-1	-35	35
30—	42	0	—	—
35—	33	+1	+33	33
40—	24	+2	+48	96
45—	27	+3	+81	243
50—	10	+4	+40	160
55—	6	+5	+30	150
60—	5	+6	+30	180
65—	1	+7	+7	49
70-75	2	+8	+16	128
Total	206	—	+195	1237

To reach the mean age at death we could add up the 206 individually recorded ages and divide by 206. But at the risk of making only an immaterial error we can shorten this process by presuming that the individuals belonging to each 5 yearly age group died at the centre age of that group—e.g., that the 42 women dying at ages between 30 and 35 all died at age 32.5. Some will have died between 30 and 32.5, some, perhaps, at exactly 32.5, some between 32.5 and 35. If the distribution is fairly symmetrical, then the positive and negative errors we make by this assumption will nearly balance out. The sum of the 206 ages at death will then be $(25 \times 1) + (12.5 \times 1) + (17.5 \times 7) + (22.5 \times 12) + (27.5 \times 35) + (32.5 \times 42) + (37.5 \times 33) + (42.5 \times 24) + (47.5 \times 27) + (52.5 \times 10) + (57.5 \times 6) + (62.5 \times 5) + (67.5 \times 1) + (72.5 \times 2) = 7670.0$ and the mean age at death is $7670.0 \div 206 = 37.2$ years. Having found the mean in this way the standard deviation could be found by calculating how much the observations in each group deviate from it and taking the square of this value. For instance the 12 individuals in the age group 20-25 died on our assumption at age 22.5. They differ from the mean, therefore by 14.7 (37.2 minus 22.5), the square of which is 216.09 , and this value we must take 12 times as there are 12 individuals with that deviation.

Following this procedure we should reach for the squares of the deviations of the individuals from their mean the following values —

$$\begin{aligned} &(-34.7)^2 \times 1 + (-24.7)^2 \times 1 + (-19.7)^2 \times 7 + \\ &(-14.7)^2 \times 12 + (-9.7)^2 \times 35 + (-4.7)^2 \times 42 + \\ &(0.3)^2 \times 33 + (5.3)^2 \times 24 + (10.3)^2 \times 27 + \\ &(15.3)^2 \times 10 + (20.3)^2 \times 6 + (25.3)^2 \times 5 + \\ &(30.3)^2 \times 1 + (35.3)^2 \times 2 = 26,310.54 \end{aligned}$$

The standard deviation is, therefore,

$$\sqrt{26,310.54/206} = \sqrt{127.72} = 11.30$$

SHORT METHOD, WITH GROUPED SERIES

This is a possible method of working but, it will be observed, a somewhat laborious way. In practice a much shorter method is adopted. The principle of this method is that instead of working in the real, and cumbersome, units of measurement we translate them arbitrarily into smaller and more convenient units, work the sums in those smaller units, and translate the results back again into the real units at the end.

Let us, for instance, replace 32.5 by 0, 27.5 by -1, 22.5 by -2 and so on, 37.5 by +1, 42.5 by +2, and so on. (The original groups must be of equal size, they were all 5 yearly in our example.) Now instead of having to multiply 27.5 by 35, for example, we have the simpler task of multiplying -1 by 35. These multiplications are made in column (4) of Table III B. Their sum, taking the sign into account (as must be done), is +195. The mean in these units is, therefore,

$$+195/206 = +0.947$$

The standard deviation can be found in these same small units, measuring the deviations of the observations from the 0 value instead of from the mean for simplicity. The squares of the deviations in these units are merely 1, 4, 9, 16, &c., and these have to be multiplied by the number of individuals with the particular deviation—e.g., 7×9 for the -3 group, 24×4 for the +2 group and so forth. A simpler process still of reaching the same result is to multiply column (4) by column (3), (instead of multiplying 7 by 9 we multiply (7×-3) by -3). This gives the figures of column (5). The sum of these squared deviations is, then, 1237 and their mean is $1237/206 = 6.0049$.

These deviations in working units have been measured round the 0 value, whereas they ought to have been measured round the mean (in working units) of +0.947. The correction as stated before, is to subtract the square of the distance between the value round which the deviations ought to have been measured and the value round which they were in fact measured, in this case the distance is $0 - 0.947 = -0.947$. The standard deviation in working units is therefore $\sqrt{6.0049 - (-0.947)^2} = 2.26$.

We have now to translate the mean, +0.947, and the standard deviation, 2.26, back into the real units. This is simply done. The mean in working units is +0.947—i.e., 0.947 working units above our 0. In real units our 0 is equivalent to 32.5, for that is the substitution we made (note, the centre of the group against which we placed the 0, not its beginning—a mistake which is somewhat easy to make). The real mean must therefore be $32.5 + 5(0.947) = 37.2$ —which is the same as the value we found by the long method using real units throughout.

The multiplier 5 is arrived at thus: the mean is found to be 0.947 above the 0 value when the groups differ in their distances from one another's centres by units—e.g. from -1 to -2—but in the real distribution their distance from one another's centres is 5—e.g., from 27.5 to 22.5—therefore the mean in real units must be 5 times 0.947 above 32.5 (if the mean in working units had been

+1 clearly the real mean would be 37.5 for the latter is the value for which +1 was the substitute—i.e. $32.5 + 5 (1)$

The rule then is this: Having found the mean in working units multiply its value by the original unit of grouping (4, 5, 10 or whatever it may be) and add the resulting figure (or subtract it according to its sign) to the value of the centre of the group against which the 0 was originally placed. That gives the real mean value. To reach the real standard deviation all that has to be done is to multiply the standard deviation as found in working units by the original units of grouping—in this case by 5. For if this measure of the scatter of the observations is 2.26 when the range is only 14 units (from -8 to +8) it must be 5 times as much when the range is really 70 units (from 2.5 to 72.5). The real standard deviation is therefore $5 \times 2.26 = 11.30$

CHECKING THE ARITHMETIC

As regards the final result it is immaterial where the 0 is placed: the same answers in real units must be reached. From the point of view of the arithmetic it is best to place it centrally so that the multipliers may be kept small. For the sake of demonstration the calculations for Table III b are repeated in Table III c taking another position for 0. This in practice is a good method of checking the arithmetic.

TABLE III c

Calculation of Standard Deviation Grouped Series

Age in years	Number of deaths in each age-group	Age in working units	(2) × (3)	(4) × (5)
(2)	(1)	(3)	(4)	(5)
0-	1	-8	-8	64
5-	—	-7	—	36
10-	1	-6	-6	36
15-	7	-5	-35	175
20-	12	-4	-48	192
25-	35	-3	-105	315
30-	42	-2	-84	168
35-	33	-1	-33	33
40-	1	0	—	0
45-	27	+1	+27	81
50-	10	+2	+20	40
55-	6	+3	+18	36
60-	—	+4	—	—
65-	1	+5	+5	25
70-75	—	+6	+12	72
Total	200	—	-217	181

From the calculations in Table III c we have
Mean in working units = $-217/200 = -1.053$
mean in real units = $42.5 - 5 (1.053) = 37.2$
(42.5 is the centre of the group against which the 0 was placed: note that the correction has now to be subtracted for the sign of the mean in working units is negative)

Mean squared deviation in working units round 0 = $1281/200 = 6.405$

standard deviation in working units is

$$\sqrt{6.405} = (1.053) = 2.26$$

(1.053 is the distance between the value of 0 from which we measured the deviations and the value from which we ought to have measured them: note that the correction is subtracted whatever the sign of the mean in working units)

the real standard deviation is $2.26 \times 5 = 11.30$
These values agree with those previously found

The Standard Deviation in Small Samples

It finally may be noted that the standard deviation found for a set of observations is an estimate of the variability of the observations in the population

or universe that has been sampled. A slightly better estimate is reached by dividing the sum of the squared deviations from the mean by $n-1$ instead of by n (where n is the number of observations). If the number of observations is large the difference is immaterial: if it is small some difference results. A simple method of making this change is to calculate the standard deviation in the way just described

and multiply the result by $\sqrt{\frac{n}{n-1}}$ e.g. the standard deviation of the 20 observations of blood pressure in Table III would be $13.55 \times \sqrt{\frac{20}{19}} = 13.90$. This correction should be applied if the number of observations is less than about 30 especially if tests of significance are to be applied.

A B H

THE FIGHT AGAINST LEPROSY

THE fourfold objective of the British Empire Leprosy Relief Association was outlined by Dr Ernest Muir its medical secretary at the annual meeting held at the India Office on April 15th. The Association is concerned with the study of leprosy and of the conditions under which it exists and spreads. It endeavours also to help the leper by care, treatment and training; to combating leprosy with a view to its final control and to interest, rouse and educate the British public in the problem of leprosy. Dr Muir said that since the inception of the Association 13 years ago a much more accurate idea had been obtained of the widespread distribution of leprosy and of the various factors which govern its incidence. Study of the disease itself had shown that while most lepers are not infectious a few highly infectious cases can spread the disease to many others and thus one generation infects the next. Those infected in childhood furnish most of the serious infectious cases. As to treatment it was now recognised that though medicines are of value the main remedy lies in healthy occupation and sound nutrition. Compulsory segregation and treatment were generally worse than useless. The leper must be led not driven; without his co-operation neither effective treatment nor limitation of the infection could be secured. Segregation by itself would never do more than touch the fringe of leprosy control—at least in poor and densely populated countries but well equipped and staffed settlements could be used as centres for an educative campaign and indeed their chief function should be to act as a centre of training and enlightenment in the district.

The annual report of the Association emphasises the fact that leprosy is a problem of colonial development. At present two types of leper institution are to be found: one is a refuge where patients are concentrated while infectious cases, not recognised as such, mix freely with the community. The other progressive type is that to which cheerful and energetic lepers are attracted mainly by the hope of recovery. It is to the organisation and multiplication of this latter type of settlement that the Association is devoting its energies and as well as to the education of all people in the nature of leprosy and the means of its prevention. Sir William Peel has succeeded Sir Edward Galt as chairman of the executive committee of the Association. He made an urgent plea for more support from the British public for the maintenance and extension of its activities.

SPECIAL ARTICLES

TREND OF THE POPULATION OF
ENGLAND AND WALES
DURING THE NEXT HUNDRED YEARS

By C A GOULD, M.C., B.Sc.

ASSISTANT IN THE STATISTICAL SECTION OF THE PUBLIC HEALTH
DEPARTMENT LONDON COUNTY COUNCIL *

For some time before the late war—in fact after the year 1870—and to a greater extent since, there has been in this country a steady drop in the fertility-rate coupled with a gradual lowering of the death rate. As a result of these two movements the population of England and Wales is rapidly ageing. To ascertain the effect of this tendency on the future age distribution of the population I have assumed in these notes that for the next hundred years the fertility rate remains at the 1933 level, and that the mortality rates are as obtaining in 1931. The 1931 census population being taken as basis, successive male and female populations at the various ages were estimated for each future census by means of the 1931 life table, assuming the 1933 fertility rates by age groups of all women (15–45) to persist and the ratio of male to female births to be 1.050.

The results are set out below. Table I gives the estimated population by age and sex at each future census up to and including the year 2031, expressed as a percentage of the corresponding population at the 1931 census, while Table II shows the percentage age distribution of the male and female populations at each future census for the next hundred years. The various changes in age distribution of the total population and in the magnitude of each age group can be conveniently analysed for each sex in the following categories: infants (0–5), children of school ages (5–15), young adult and early middle age workers (15–45), middle age workers (45–65), and pensioners (65+).

TABLE I

Estimated population by age groups at each census date during the next hundred years expressed as a percentage of the corresponding age group population in 1931

(1) *Infants* (0–5)—This group comprised 8 per cent of the whole population as regards males and 7 per cent

* The opinions and conclusions expressed herein are my own and the London County Council accepts no responsibility for them.

as regards females in 1931. In the year 2031 these percentages will each have dropped to 5. Also by this time the number of males of this group will have steadily fallen to 38 per cent of their number in 1931 while the females will be reduced to 37 per cent.

(2) *School-children* (5–15)—In 1931 the males of this group will comprise 12 per cent of the total male population and the females 11 per cent of the female population as compared with 17 per cent and 16 per cent respectively in 1931. Again the males and females of this group will, as in the group above, steadily decrease in numbers during the period, in the year 2031 each will be only 36 per cent of the 1931 population of this group.

(3) *Young adults and early middle-aged* (15–45)—In 1931 this group formed 47 per cent of the total population for each sex, in the year 2031, however, the males will be reduced to 40 per cent and the females to 38 per cent. Moreover, the males will by then have fallen to 40 per cent and the females to 41 per cent of their numbers respectively in 1931.

(4) *The middle-aged* (45–65)—The percentage of total population formed by this group will increase during the next hundred years from 21 to 28 for males and from 22 to 28 for females. In the year 2031, however, the males will be reduced to 71 per cent and the females to 64 per cent of their numbers respectively in 1931, the census maximum of 129 per cent for males being reached about 1971 and that of 126 per cent for females in 1961, some ten years earlier.

TABLE II

Percentage age-distribution of male and female populations at each census during the next hundred years

Census	Age	0–5	5–15	15–45	45–65	65+	All ages
1931	M	8	17	47	21	7	100
	F	7	16	47	22	8	100

(5) *Pensioners* (65+)—Male pensioners will increase from 7 per cent to 15 per cent of the total male population during the next hundred years, while the females will increase from 8 per cent to 18 per cent. The numbers of both sexes will also rise rapidly until the year 1951, when the males will be 186 per cent and the females 190 per cent of their respective numbers in 1931. By the year 2031, however, these percentages will have dropped to 122 and 117 respectively.

The maximum total population, 19,600,000 males and 21,200,000 females, will be attained about the year 1944 and at the end of a hundred years the total population will be only about half of that in 1931—namely, 10,280,000 males and 10,650,000 females approximately.

Diagram showing the population of England and Wales at twenty year intervals during the next century. The calculations are based on the assumption that the fertility rate is the same as in 1933 and the mortality rate the same as in 1931. Each homonculus represents one million persons.

The effect of these changes in the number and age distribution of the population will be far reaching. The reduction in the number of females of the child bearing ages (15-45) will mean fewer babies and eventually fewer school-children; this in turn may lead to fewer schools and teachers in the years to come. Moreover any further lowering of the fertility rate coupled with a drop in the number of potential mothers and fathers would cause a still further reduction in the number of births.

As the older generations die off the fall in the number of young adults of both sexes will cause a dearth of employees and potential purchasers of food and commodities. Trade will consequently suffer on the other hand wages will tend to increase. Another serious aspect is the financial effect of an increasing pensioner group (age 65+) coupled with a decreasing contributor group (aged 15-65) on annuity and pension funds. One thing is certain—namely that in future the annual pension will be much greater for example at the end of the period it will be more than twice the cost in 1931.

The flow of population to the large towns has gradually drained the countryside of its workers and the steady decrease in population in the future will accentuate this depopulation of the rural districts more than ever. Unless a determined move is soon made to repopulate country districts our supply of home-grown food already inadequate to feed the nation will tend to disappear. It may also be asked how we are going to maintain our fighting forces with a regular supply of recruits and man our merchant service with seamen in the future in view of the certainty of a steady fall in the number of young male adults. These problems will force themselves on the attention of our politicians before many years

are past one of them—that of defence—is already causing anxiety.

In this investigation the possible effects of migration have been ignored since it is obviously impossible to attempt to forecast the extent of emigration that may take place from this country in the coming years. There will doubtless be determined efforts in the near future to increase the outward flow of population to various parts of the Empire especially of young adults and children. This of course will add to the increasing high proportion of persons over 45. It is unlikely that fertility rates will fall much lower—there are already signs of a slight upward tendency—and it is doubtful whether there will be a much further reduction in the general death rate in view of the steady increase in the percentage of total population in the older age groups amongst which the majority of deaths occur. Should however an improvement in fertility take place in the future this will be largely counteracted for some years to come by the increase in the death rate. We can therefore assume that apart from the effects of future migration the above estimates give a reasonably accurate forecast of the trend of the population of England and Wales during the next century unless significant changes in fertility and mortality rates occur during the period.

CHELMSFORD NEW HEALTH CENTRE—The mayor of Chelmsford has opened a new public health department where clinics will be held and the staff of the borough medical officer housed. There is a health visitors room a treatment department in which minor ailments are dealt with a dark room a consultation room a dental department and a recovery room. The cost has been £5000.

MANCHESTER MEDICAL LIBRARY

THE question of increased accommodation for the storage of books and of improved facilities for their easy use is a problem almost as pressing to medical schools as is that of more laboratory and lecture room accommodation. Manchester University is recognising this in its present appeal for money and in its plans for the future. Its medical library to which, in addition to its own staff and students, the members of the Manchester Medical Society have access, and which is to a considerable degree supported by the latter, is housed in the university medical school. But the present accommodation is by no means all that could be desired. Harvey Cushing, himself an eminent authority on medical books, has described the library as one of the best he had seen but as one of the worst housed. The acids of the Manchester atmosphere, some of them perhaps from the university's own chemical laboratories, assisted by the fumes of the gas with which the rooms were for many years lighted, have played havoc with the bindings. Space too is deficient, both for qualified readers and for the students who are using the library in increasing numbers and who would use it still more if elbow room and comfort were improved. The fact that the students' reading room acts as a passage for access to the general room and committee room tells its own tale. A lecture theatre is also urgently required.

The library, which claims to be the largest medical library in England outside London, contains some 75,000 bound volumes as well as many thousands of pamphlets which are only now in process of being sorted and catalogued. One of the avowed objects of the Manchester Medical Society when it was founded in 1834 was "to establish a medical library and reading room." For many years its progress, at first in a private house in Faulkner street, then in the Royal Institution (which is now the City Art Gallery) was slow. In 1875 an arrangement was arrived at by which Owens College housed the books in its newly built medical school at the back of the Oxford road buildings, and provided the medical society with headquarters. The college gave a grant to help in maintenance and as this grant was augmented it obtained increasing rights for its staff and students. As the library grew the society found it more and more difficult to maintain its standard of efficiency, until in 1930 it was handed over to the university, the members of the society retaining their right to the use of the books and accommodation. As the gift implied that the society could not now break away taking the books with it, it became worth while for the university to develop the library and to spend money in housing it properly. The university has allotted a site for it conveniently close to the medical school.

The library, as it stands, is largely the result of the work of Dr Thomas Windsor (1831-1910), a bibliophile of bibliophiles. Valuable collections have been given, one by Dr Samuel Crompton, another by Dr Charles Clay of ovariotomy fame, others by the Royal Infirmary and the Manchester St Mary's Hospitals. Many rare books are to be found on the shelves. Among the menubula are an Italian copy of "Guv de Chauliac" (1480). Other early books are a 'Herbal or Boke of the Properties of Herbes' (1548), of which no other example is known, and a copy of Wolveridge's "Speculum Matris or The Expert Midwives Handmaid" (1671) which is very rare. The library possesses

also a presentation copy of Beaumont's work on Alexis St Martin, and two copies of Parkinson's "Shaking Palsy," both rare works. Apart from books there is John Hunter's grandfather clock, his dinner bell, and the seal of his diploma as Fellow of the Royal College of Surgeons in Ireland, all of which were acquired from the family of Sir Richard Owen, to whom they came through his marriage with the daughter of William Clift who assisted Hunter.

In part owing to want of space in the main library rooms, and in part for convenience, a system of departmental libraries—physiology, anatomy, pharmacology, gynaecology, cancer, public health, and dentistry—has been inaugurated, these hold all the books on their own subjects and facilitate study though they create difficulties of control. Another special section is given up to local medical history—of Manchester in particular, but also of Lancashire and Cheshire in general—which contains some 1100 volumes and 230 boxes of unbound material.

THE HAWKING OF DRUGS

LAST year a new law regulating the sale of drugs came into force in France. This law was the inevitable reaction to the self prescribed pharmacological orgies in which the country has indulged with ever growing zest. The law strikes at the sale of drugs outside the chemist's shop which, if the chemist himself is on duty, is supposed to serve, if not as an absolutely fool proof safety valve, at least as a check on the public's ardently misguided search for health in a bottle. The new law also attempts to put a spoke into the wheel of the circularising "herborist" who, through the post and persuasive touts, offers Nature's cures without discrimination. A recent number of the *Siccle Médical* reports an important judgment of the *tribunal correctionnel* of Nancy. In this town a certain doctor of pharmacy was prosecuted for the sale of drugs under conditions infringing the law of Sept 4th, 1936. On the first occasion he was acquitted by the tribunal which found that he had acted in good faith. Regarding this judgment as an incentive he employed nine motor lorries on regular circuits of neighbouring villages, collecting orders and distributing goods already ordered. These lorries were in effect chemist's shops on wheels without a duly qualified chemist to put on the brake. The leniency shown by the tribunal on the first occasion was not repeated, and the chemist was fined 300 francs and ordered to pay 10,000 francs damages to the *Syndicat des pharmaciens de Lorraine*. The judgment in this case should prove an obstacle to the sale and delivery of pharmacological preparations at the customer's door as though they were the daily necessities of life.

THE FUTURE OF NURSING IN THE AIR

Dr P. Bichague, who is "vice président délégué" of the Comité Central d'Aviation Sanitaire, and who has done much to organise a network of first aid posts on the French main roads, is not a little concerned about the future of nursing in the air. During the past two years more than 200 French nurses have passed all the tests required of them for air ambulance service, and now they find there is little scope for their activities in this sphere. From a national

point of view their sacrifices in time and money and energy have certainly not been wasted for these enterprising young women have set an excellent example to their brothers and other members of the *séxe faible*. The authorities are not to be blamed unreservedly for having encouraged young nurses to qualify for duties of a hypothetical character and it was made plain enough from the outset that the emergencies in which air nurses might be called to serve might never materialise. But the fact remains that these nurses have found no immediate return for a relatively costly investment. Dr Béhague is inclined to think that there has been a certain fundamental misconception about first aid in the air. As he points out both peace time and war time emergencies may make calls on air ambulance space so great that it will often be given to two patients rather than to one patient plus a nurse. If nursing is required in a particularly important case this can be given by a doctor. His advice to would be first aid workers in the air is in effect that they first learn to fly and that they then master whatever may be required of them as first-aid attendants. Merely to qualify as an air nurse and not as a pilot is to risk being left behind on the ground in an emergency. Experience with first aid on the highways has convinced Dr Béhague that the most satisfactory arrangement is to teach the men in charge of first aid posts on the roads the elements of first aid which can thus be given far more promptly than were the injured to be cared for by skilled first-aid workers rushed up from some distant centre. And in this connexion he compares the man on a highway present at the time of an accident with the pilot who has learnt not only to fly but also to nurse.

It is probable that the majority of Dr Béhague's 200 nurses have followed a course of a few hours in first aid or at most have completed a nursing course of only a few months and the guess may be ventured that few possess the official nursing diploma. It is not surprising therefore that these 200 have been unable to find employment in a country where the State regulates the training of nurses and has created a State diploma.

COMPULSORY ANTI TYPHOID AND ANTI DIPHTHERIA VACCINATION FOR MEDICAL STUDENTS

It will be remembered that last summer the attention of the French Academy of Medicine was drawn to the high diphtheria rate among medical students and the need for protecting them against it by artificial immunisation. Dr Clément's advocacy of this measure was supported by no less an authority than Dr Rouvillois who went one better by advocating triple associated vaccination of medical students against typhoid, diphtheria and tetanus. The commission created by the Academy was remarkably strong and representative and its rapporteur was Prof Tanon. When it met in February of this year it decided that compulsory vaccination against tetanus might be dispensed with considering how rare this disease is in medical students. On the other hand it was agreed that associated vaccination against typhoid and diphtheria should be recommended as a compulsory measure early in the medical curriculum and without recourse to the Schick test. The Academy of Medicine has now adopted the findings of its commission and the next step will presumably be their presentation to the Ministers of Public Health and National Education.

NOTIFICATIONS OF THE CAUSES OF DEATH

The inability or unwillingness of many doctors to state in writing why some of their patients died

has for many years been a thorn in the flesh of the public health authorities. In 1927 there were as many as 70 000 deaths whose cause was not accurately specified in the death certificates. In 1933 this figure rose to 118 000 or 17 per cent of all the deaths recorded in this year. Since Jan 1st 1929 a more or less concerted effort has been made by five departments or counties to reform matters in this respect and the departmental inspectors of hygiene have co-operated with medical practitioners so effectively that the proportion of deaths from unknown causes has been reduced to less than 5 per cent. The principles on which this reform has been based are now to be introduced in all the other departments in France as from July 1st 1937. In the past vagueness in the wording of death certificates has often reflected a doctor's sense of obligation to professional secrecy and it is to ease his conscience in this respect that in the future death certificates will be so drafted that the part showing the cause of death will be detached from the part on which the name of the dead person is inscribed. There will also be such a speeding up of the passage of the death certificate to its final destination that if it is faultily worded it can promptly be referred back to its author.

IRELAND

(FROM OUR OWN CORRESPONDENT)

A REVIEW OF THE YEAR

THE introduction of the estimate for the Department of Local Government and Public Health by the Minister gave an opportunity in the Dáil last week for a general discussion of questions of public health. The total grant asked for was £1,269 008 which included a sum of £769 432 for housing and £327 006 for social services. The Minister stated that the administration of public health was now supervised in every county by a county medical officer of health. Throughout the country the organisation of public health measures was being gradually perfected and further improvements in the public health might be hoped for. The vital statistics for 1935—the latest available—showed a slight rise in both birth rate and death rate. The former had increased from 19.49 per 1000 in 1934 to 20.01 in 1935 and the latter from 13.15 to 13.08. The increase in the death rate was largely due to a high incidence of the principal infectious diseases which were more numerous than in 1934 being 1865 as compared with 1369. Three cases of typhus fever were recorded the lowest number in the history of the country. The incidence of diphtheria had diminished the decrease being greatest in those areas where the most intensive immunising campaigns had been carried out. There had been heavy mortality from measles during the year the number of deaths being 316 whereas they were 50 in the previous year. Infant mortality shared in the general increase of the death rate being 68 per 1000 births as compared with 63 in the previous year. The greater mortality among infants was chiefly due to congenital defects and to outbreaks of diarrhoea and enteritis. The Minister hoped that the carrying into effect of the regulations made in pursuance of the Milk and Dairies Act 1935 would go a long way to reduce the incidence of these diseases. The infant mortality was highest in the urban areas. In Waterford it was 126 per 1000 birth in Kilkenny 110 in Limerick 106 and in Wexford 107. The rate in Dublin had risen from 80 in 1934 to 91 in 1935. Valuable work for the safeguarding of

infant life was being carried out under approved maternity and child welfare schemes in many of the urban areas and in a few counties. Approved schemes for the supply of free milk to poor children had been in operation in all areas except two urban districts in which the local authorities declined to avail themselves of the amounts of money allocated. School medical inspection was now carried out in every county, and was associated with medical and surgical treatment for certain defects. School meals were now supplied by 51 local authorities, the number of meals supplied in 1936 being approximately 4,231,872.

There was an increase in the number of deaths from tuberculosis from 3520 to 3770, the death rate being much higher in the urban than in the rural areas. There had been a grant from the Hospitals Sweepstakes Fund of £10,000 toward medical research, and a council to administer the Fund had been appointed. A sum of £10,000 had also been allocated for the establishment of a hospital library service. The Minister dealt at length with what had been done in regard to housing. The total number of houses built since 1932 would appear to be 14,895 in urban areas and 8662 in rural areas.

SITUATION OF THE HOSPITALS

In the subsequent discussion the Minister was questioned as to his intentions in regard to the development of the hospital system of the country, and specially with reference to the Dublin hospitals. Dr Rowlette (Dublin University) drew attention to the report of the Hospitals Commission which had been in the Minister's hands for some 18 months. The report had recommended a certain line of development of the Dublin voluntary hospitals but the Minister's decision had not yet been given. The hospitals concerned were at a standstill through not knowing what their future was to be. At the same time the pressure on their bed accommodation was steadily increasing. Not only was the population of Dublin growing rapidly but the desire and need for hospital treatment in preference to home treatment were also growing, and would continue to grow. He emphasised that the Sweepstakes were organised by those interested in the voluntary hospitals for the aid of the voluntary hospitals, and the voluntary hospitals had a primary claim on the Sweepstakes Funds.

Thus contention was admitted in his reply by the Minister. He agreed that the voluntary hospitals "had, ethically and in all justice, a right to primary consideration when distributing the Hospitals Sweepstakes Funds." He declared also that it was not his intention to spend on the hospitals of local authorities more than one third of the net amount received out of the Hospitals Sweepstakes Funds for hospitals.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg Lt Comdr D R F Bertram to *St Angelo* for R N Hospital Malta.
Surg Lts C J Roberts to *Halcyon* and F Bush to *Pembroke* for R N B.
Surg Lt (D) D D Craig to *Wildfire*.

ROYAL NAVAL VOLUNTEER RESERVE

Surg Capt L S Ashcroft to *President*.
Surg Lt Comdrs E F St J Lyburn to *Resolution*, S B Borthwick, F L Stabler, T C Larkworth to *President*, and C Seeley to *Royal Sovereign*.
Surg Lts G L Foss to *President* and D R Matland (provs.) to *Victory* for R N Hospital Haslar.

ARMY MEDICAL SERVICES

The War Office announces that Brevet Col R C Priest, Hon Physician to the King, has been selected

for appointment as Professor of Tropical Medicine, Royal Army Medical College, and Consulting Physician to the Army, with effect from June 6th, 1937, in succession to Col J Heath Spencer, Hon Physician to the King, who is retiring.

ARMY DENTAL CORPS

Lt T A Smitham to be Capt.

ROYAL ARMY MEDICAL CORPS

TERRITORIAL ARMY

Col A P Watson OBE, TD, having attained the age limit, retires and retains his rank, with permission to wear the prescribed uniform.

Lt T W Preston to be Capt.

J L Murray (late Offr Cadet Durham Univ Contgt (Med Unit) Sen Div, OTC) to be Lt.

A D Kelly (late Cadet CSM, Durham Sch Contgt, Jun Div, OTC) to be Lt.

TERRITORIAL ARMY RESERVE OF OFFICERS

Capt H W A Post from Active List to be Capt.

ROYAL AIR FORCE

Wing Comdr H S C Starkey, OBE, to No 3 Flying Training School, Grantham, for duty as Medical Officer.

Squadron Leader P D Barling to RAF Station, Feltwell, for duty as Medical Officer.

Flight Lt G H J Williams to Home Aircraft Depot, Henlow.

Flying Offrs N P R Clyde to RAF Station, Waddington, and D F Shaw to RAF Station, Harwell.

Dental Branch—Flight Lt W D Guyler to RAF Station, Seletar, Straits Settlements.

INDIAN MEDICAL SERVICE

Maj Gen Sir C A Sprawson, Kt, CIE, K.H.P., retires. Brevet-Col A A C McNeill has been appointed as Deputy Director of Medical Services at Army H.Q., New Delhi, in place of Maj General F D G Howell, DSO, VC, K.H.S., transferred to Aldershot as D.D.M.S. in March last.

Majs to be Lt Cols S L Patney, D N Bhadran, B Basu, OBE, M A Jafarey, G Verghese, and A D Loganadan.

Col W H Hamilton, CIE CBE, DSO, K.H.P. to be Maj Gen.

Lt Col A F Babonau, CIE, OBE, to be Col.

Lt Col T L Bomford retires.

Capt K Cunningham resigns his commn.

Indian Medical Department—Asst Surgns (1st Cl) to be Lts (Sen Asst Surgns) W G Sherard and S G Jackson. Lt (Sen Asst Surg) A E Gomez, MBE, retires.

COLONIAL MEDICAL SERVICE

Dr B S Jones and Dr G E McVittie have been appointed Medical Officers, West Africa, and Miss M J Lyon, M.B. B.S., Medical Officer, Malaya. Sir Robert G Archibald, CMG, DSO, MD, has been appointed Medical Superintendent, Chacachacare Leprosy Settlement, Trinidad. Dr G E Craig becomes Deputy Director of Medical Service Gold Coast, Mr R M Dannatt, Resident Surgeon, Colonial Hospital, Grenada, and Dr L G W Urck (Medical Superintendent, Chacachacare Leprosy Settlement) Medical Officer of Health, Trinidad.

DEATHS IN THE SERVICES

The death occurred at Southsea on April 11th of Surgeon Captain HUGH PRIDEAUX TURNBULL. Born at Plymouth in June, 1873, he was son of the late Alexander Turnbull, MD of the Naval Medical Service. He was educated at St Paul's School (1884-90) and St George's Hospital London, qualifying M.R.C.S. Eng. in 1897. He at once entered the Navy, was appointed surgeon of the sloop *Torch* (101 men), and landed at Samoa in 1899 for service with the Naval Brigade, and was mentioned in dispatches. He became surgeon commander in May, 1913. He served in the European war on H.M.S. *Roxburgh* (1914-16), and then was put in charge of the Royal Naval Hospital, Bermuda (1916-19). In 1922 he was squadron medical officer in the battleship *Barham*, and he subsequently held the post of professor at H.M. Navigation School, Portsmouth.

PUBLIC HEALTH

MILK EXAMINATION

A COMPARISON OF THE PLATE COUNT AND REDUCTASE TEST

By J STEVEN FAULDS M D

PATHOLOGIST TO THE CUMBERLAND INFIRMARY CARLISLE

DURING the past year several papers have been published comparing the methylene blue reductase test with plate count and *B. coli* estimation. Opinions differ about their merit but it is agreed that the results of the plate count are not consistent. The most obvious reasons for the inconsistency are the difficulty of obtaining an accurate representative sample of a fluid difficult to shake efficiently the difference of temperatures and the agitation of samples during transit, which quickly changes their bacterial content.

To ascertain how far the results of the methylene blue reductase test and the plate count are in agreement I have examined 1500 samples by both of them (end of March to end of November 1936). For the reductase test the technique described by Prof G S Wilson (1935) was observed particularly regarding methylene-blue (Dr Orla Jensen Stockholm) water bath temperature and half hourly inspection. The plate count was carried out according to the Ministry of Health Memorandum (1923) the media being simple Lab Lemco and not a milk enriched variety. Plates were made from dilutions 1/10 and 1/100 in 15 cm plates and 1/1000 and 1/10 000 in 11 cm plates and a count made of each plate unless the total number of colonies made the counting an impossibility. If any plate showed a substantial discrepancy it was discarded otherwise the total count was struck from an average of the most countable plates. *B. coli* was estimated by taking 1 ml. of 1/10 1/100 and 1/1000 dilution in standard McConkey fluid medium. Two technicians did all the plating out and periodically the accuracy was checked by duplicating a sample of milk when the figures obtained were always approximately the same.

In comparing results of the reductase test with the count and *coli* I found that there were 23.3 per cent of samples which passed one test but not the other. The inconsistency was greatest in June and July when we had warmer weather and it evidently depended upon the temperature of the milk on arrival. A total of 5.3 per cent passed the reductase test but failed by the count and *coli* estimation (accepting the tuberculin tested standard 1930 of 200 000 per ml. and *coli* negative in 1/100 ml) and of these 79 milks 80 per cent failed owing to there being *coli* present in 1/100 ml. The remaining 17 per cent passed the count and *coli* standard and yet failed by the methylene blue reductase test. The reductase test was therefore not stringent enough in 5 per cent of milks and too severe in 17 per cent. I then tabulated all those samples which failed by the reductase test and which had not more than 100 000 organisms per ml. and were *coli* negative in 1/100 ml according to the time at which the colour was discharged. There was no apparent correlation. Evidently the time of reduction by the reductase test did not always depend on the total number of organisms. When however all the milk specimens were grouped according to the temperature on arrival and a graph drawn of the discrepancies at each

temperature a curve was produced which while irregular showed that there was a higher percentage of discrepancies at higher temperatures (see Figure). When the discrepancies were subdivided into those that passed the count and *coli* standard and failed

Graph showing the percentage of discrepancies at various temperatures. Continuous line - total discrepancies. Interrupted line - count and *coli* pass reductase test fail.

by the methylene blue reductase test a similar curve was obtained. At a temperature around 13°-16° C there was only 16 per cent of difference between the two results. When the temperature of the milk on arrival was 20° C there was a total difference of 27 per cent.

DISCUSSION

The cause of the reduction of the methylene blue is obscure but with aerobic cultures and correctly performed the test is alleged to be an index of bacterial metabolism. Different organisms have different reducing powers and it has been found that *Streptococcus lactis* reduces even more rapidly than *B. coli* given an equal amount of equivalent suspensions and that strains of homolytic streptococci vary considerably in their reducing time. Some are as active as *coli* while others do not reduce within the six hours. On the whole however we can accept the fact that a milk incubated aerobically that reduces methylene-blue does so because of bacterial growth though the converse does not hold as Malcolm and Leitch (1936) have proved.

When it comes to comparing the plate counts with the reductase test difficulties arise especially when the results of different laboratories are compared. Wilson (1935) states that the experimental error in plate counts is high and that any given count may be either half or double that shown. I tried to check this observation but never managed to obtain a difference of anything like this figure. The error arises more in the dilutions than in the readings of the plates and this observation supports the work of Mattick and others (1935) who found that two observers using exactly the same technique and examining the same milk at the same time got results as close as did one observer plating a milk out in duplicate. On the other hand the results obtained by different workers using the same technique on identical samples of milk

in different laboratories were by no means the same, because of the different conditions the milk was subjected to before being tested. Though Wilson does not regard the tests as strictly comparable, it is reasonable to expect that different laboratories submitting samples of milk to both tests will obtain similar results, but even this does not happen. The accompanying Table compares the results of four independent analyses. Malcolm and Leitch (1936) found 45 per cent of discrepancies, Tudor and Thomas (1936) 22 per cent, and I have found 22 per

Table showing results of comparisons between reductase and plate count tests

—	Number of samples	Per cent failed by reductase and passed by plate count and coli	Per cent failed by count and coli and passed by reductase	Total discrepancies per cent
Malcolm and Leitch	7248	11	34	45
Thomas and Tudor	400	9	13	22
Nichols and Edwards	1000	24*	22*	10
Faulds	1500	17	5	22

* No coli estimation

cent, Nichols and Edwards (1936) found that of milks with counts between 30,000 and 200,000, 24 per cent reduced methylene blue while of milks with a count of over 200,000 22 per cent failed to do so, but when these were classified into readings above and below 200,000 the error was reduced to 10 per cent. These observers did not include the presence of *B. coli* in 1/100 ml. nor did they adhere to the standard time the milks were to be kept, according to the memorandum, differentiating morning from evening samples. The time the methylene blue was read was 5 and 6 hours, not 4½ and 5½ as stipulated. The figures of Malcolm and Leitch show much higher plate counts than I obtained, but that could be accounted for by the enriched medium used.

The plea that the reductase test is better than the older method must be based on its being either simpler to perform or more accurate. The accuracy I doubt, for to quote Breed (1936), New York State agricultural bacteriologist, "the mere fact that duplicate results of the reductase test are generally uniform does not, of course, prove anything regarding the accuracy of the results." The advantage must be in simplicity. The reductase test is much easier to perform and saves time and material, it can be carried out by semi skilled labour unless we include the coliform test. By including this, which I feel is necessary for accuracy, the dilutions entail time, material, and skill, and the end result is a test requiring the same skill, time, and material as the old plate count and coliform test.

The argument of economy is doubtful. The average charge for the plate count and coliform test was 3s 6d and the suggested charge for the reductase test alone 1s, or, when the coliform test is added, 1s 6d. The cost of the material is less than 1d but the overhead charges and arrangements for collecting samples and supplying outfits justifies this charge. The laboratory charges however are only a fraction of the cost of sampling. In some areas the council employs a whole time sampling officer who has to take morning and evening samples of milk. In other areas, as in Cumberland where the

area of milk production is large, the sampling is done by the local councils through their sanitary inspectors and a grant is made by the county council to the inspectors for every sample taken. In the case of rural samples this grant is 5s, but in urban samples it is 1s. In Westmorland, the sum is a flat rate of 2s 6d per sample. Now a reduction of 3s 6d to 1s will be no economy if the Ministry's recommendation of sampling each milk twelve times a year be carried out, for the cost will rise in proportion.

CONCLUSIONS

The methylene blue reductase test is much simpler to apply than the plate count and it yields 75 per cent of comparable results. On the whole it is a more stringent test in warm weather and less stringent in cold weather—the opposite of what is needed. The arguments in favour of its adoption as an economy are weak if the cost of the collection is taken into account. If the coliform test has to be performed in addition, the advantage of the reductase test over the plate count and coliform test is not so great as would appear.

I wish to acknowledge with thanks the help and stimulus I have received from Mr R. Simpson, F.R.C.V.S., county veterinary officer for Cumberland.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED APRIL 3RD, 1937

Notifications.—The following cases of infectious disease were notified during the week. Small-pox, 0, scarlet fever, 1001, diphtheria, 926, enteric fever, 16, pneumonia (primary or influenzal), 1937, puerperal fever, 27, puerperal pyrexia, 110, cerebro spinal fever, 24, acute poliomyelitis, 4, acute polio-encephalitis, 1, encephalitis lethargica, 3, dysentery, 9, ophthalmia neonatorum, 108. No case of cholera-plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on April 9th was 3314 which included scarlet fever 856, diphtheria 961, measles 45, whooping cough 530, puerperal fever 16, mothers (plus 11 babies) encephalitis lethargica 283, poliomyelitis 1. At St. Margaret's Hospital there were 18 babies (plus 8 mothers) with ophthalmia neonatorum.

Deaths.—In 123 great towns,* including London, there was no death from small pox, 2 (0) from enteric fever, 23 (0) from measles, 5 (1) from scarlet fever, 31 (8) from whooping cough, 20 (4) from diphtheria, 47 (14) from diarrhoea and enteritis under two years, and 101 (17) from influenza. The figures in parentheses are those for London itself.

Barking and Cardiff each had 1 death from enteric fever. Six deaths from measles were reported from Birmingham, 3 from Walsall. Fatal cases of whooping cough were scattered over 21 great towns. Brighton reported 3. Fatal diphtheria was reported from 20 great towns. Liverpool had 3 deaths.

The number of stillbirths notified during the week was 274 (corresponding to a rate of 43 per 1000 total births), including 38 in London.

* Twickenham with a population of 86,600 became a great town on April 1st as the result of a change of boundary.

PANEL AND CONTRACT PRACTICE

Panel Practitioner Fined for Non attendance

A DOCTOR has been fined £5 by the Middlesex insurance committee for breach of the medical service regulations. There was evidence that she was called at 6.40 P.M. on Dec. 19th to visit a young woman who was a panel patient. She did not come and was sent for again at 10 P.M. Again she did not come but left a prescription on the window sill and gave the parents a bottle of medicine and some oil to rub on the patient's chest. She excused herself on the plea that she was tired after a very busy day. The father tried to obtain another doctor's services in vain. Next morning the doctor called at 10.30 diagnosed bronchitis asked for the prescription which had been left on the window-sill altered it and said she would send a nurse. At 12.30 P.M. she came again in answer to a fresh summons sent for an ambulance and had the patient removed to hospital. At the hospital the parents were told that it was too late to do anything more the patient died at midnight of the same day from pneumonia. The amount of the fine may perhaps be deemed to indicate that the most serious view was not taken of the practitioner's default. While the insurance committee evidently could not overlook what had occurred those who know the strain under which practitioners work at times when ill health is specially prevalent may be ready to appreciate that moments may come when the doctor is genuinely too tired to attend.

Dispensing in Scotland

SOME statistics relating to the Scottish drug bill were recently analysed by the superintendent of the Central Checking Bureau in Scotland. It appears that during 1936 some four and a quarter million prescription forms were received from many sources: (1) 54 insurance committees in Scotland (2) the government of Northern Ireland (3) various local authorities (4) the Ministry of Pensions (5) public medical services. Only the first two categories include National Health Insurance prescriptions. The receipts of Scottish panel chemists have risen by 79 per cent in the 20 years from 1915 to 1935 and by another 9 per cent in 1936. The average price per form had increased from 0.74d. in 1915 to 13.32d. in 1935 and 13.60d. in 1936. These figures did not include the cost for insulin. In 1935 the cost per person in Scotland for drugs and prescribed appliances ranged from 17.17d. to 52.76d. with an average of 23.17d. In England the cost ranged from 23.1d. to 52.8d. with an average of 36d. Frequency in Scotland ranged from 1.10 to 2.03 with an average of 1.73 as compared with 2.69 to 0.70 and 4.60 in England. The average price per prescription form ranged from 11.21d. to 17.90d. with a general average of 13.32d. The comparable English figures were 7.1d. 10.1d. and 7.38d.

SOME insured persons were the recipients of expensive prescriptions for example six prescriptions for amino acetic acid cost in all £20 10s. 6d. one insured person still under treatment received during eleven years 1083 lb. of an ointment which cost £138. one insured person in a period of three years received insulin liver extract and mixtures at a total cost of £235.

Prescribing in Lancashire

THE Lancashire panel committee has been examining the report issued by the insurance committee

in April 1936 on the cost of drugs and medicines prescribed for insured persons in the county. The cost of supplying drugs to the insured population has increased steadily during the last twelve years not only in Lancashire but in all parts of the Kingdom. The committee are anxious to help to prevent further increases and indeed to bring about a reduction in cost if this can be done without reducing therapeutic efficiency. In Lancashire frequency has increased from 3.87 in 1923 to 5.03 in 1935 but the committee point out that this latter figure is only 0.2 higher than in London and is 1.40 lower than in Manchester. The increase corresponds to that for visits or consultations all over the country. The Insurance Acts Committee showed that in 1923 each insured person was seen on an average 3.75 times and in 1935 the figure had risen to 6.11. The increase in frequency is attributed entirely to the altered habit of the insured population and to the increased amount of work done by the doctors. Recent health propaganda has caused the insured person to become health conscious and even disease conscious. He takes more notice of slight ailments and consults his doctor earlier and more frequently. Gradually the insured population is becoming composed of persons who never at any time have paid private fees for medical attendance whereas the original insured population had already acquired an economic habit in this respect. It is likely therefore that the frequency factor has not yet reached the peak and will not do so until the entire insured population consists of persons who have never received medical attendance in any other way. The panel committee express the opinion that the frequency factor is almost entirely outside the control of the doctors.

With regard to the total cost per prescription the dispensing fee is a fixed cost practically constant and is also entirely outside the control of the doctor. The ingredient cost however was 3.79d. in 1935. A number of prescriptions are for specially expensive products—e.g. about 100 autogenous vaccines (two guineas each) are prescribed every year and about 160 stock vaccines at half a guinea. A few months ago the attention of the Lancashire panel committee was called though not by way of complaint to a prescription for Kellon's serum costing over £7. One doctor ordered in seven days for one patient oxygen costing £75. Many prescriptions are for expensive products for intramuscular or intravenous injection and other special prescriptions cost four to five shillings. If the cost of expensive but perfectly justifiable prescriptions were separated before the average for the ordinary prescription was taken the ingredient cost of a 10 oz. bottle of medicine would probably be somewhere about 2.5d. The use of proprietary products does not seem to have been an important factor in the increased cost of prescribing but the committee believe that some slight economy might be effected by the avoidance when possible of the use of such remedies. In their opinion the occasions on which the ordering of proprietary products can be justified are comparatively few.

The committee observe that in May last the Minister of Health stated in reply to a question in the House of Commons that he had received a report from the Lancashire insurance committee to the effect that there was unnecessary prescribing by doctors in Lancashire. So far as the panel committee were aware the insurance committee had expressed no such opinion.

GRAINS AND SCRUPLES

Under this heading appear week by week the unfettered thoughts of doctors in various occupations. Each contributor is responsible for the section for a month, his name can be seen later in the half yearly index

FROM A TADDYGADDY

III

'The wisdom of a learned man cometh by opportunity of leisure, and he that hath little business shall become wise

THAT, oddly enough, was written also by Ben Sira, and in the very same chapter as that into which we have dipped already. It seems untrue at first, but when we go on reading we find out what he really was getting at. He was thinking of leisure from bodily toil. He had few illusions concerning that. "Send him to labour that he be not idle, for idleness teacheth much mischief," he wrote of the slave. Apparently there were people in his neighbourhood, men in advance of their time, who were trying to set up some sort of Labour Party. Ben Sira did not at all approve. "How," he asks, "can he get wisdom that holdeth the plough, and that glorieth in the goad, that driveth oxen, and is occupied in their labours, and whose talk is of bullocks? So every carpenter and workmaster that laboureth night and day. They shall not sit in the judges' seat, nor understand the sentence of judgment: they cannot declare justice and judgment, and they shall not be found where parables are spoken."

* * *

That is not quite in accord with modern ideas, though there are plenty only too ready to agree. How does the suggestion affect us? Few of us in active practice have much leisure, yet some of us do become wise in spite of our considerable business. Indeed it is due largely to our press of work that we acquire wisdom, or at any rate a useful store of common sense. That, I have felt for many years, is not used as freely as it should be. There is so much more we doctors might do, so much we have to offer, in the public service. Some of us serve on town councils, some as magistrates, but relatively few of us do that. The plea put forward for not doing it is that we have no time to spare. Is that wholly true? My experience is that there is always time for what one really wants to do. I say that advisedly. I have been a town councillor, I am a magistrate, and I have never in my life been leisured. The years during which I was a town councillor were extremely busy ones, but there was always time for a meeting. Only very seldom were the meetings barren of interest. I found my brethren, especially the more aged of the aldermen, fascinating to study, and I made a collection of mayoral impressions that is quite beyond all price. That a doctor should be interested in the doings of a health committee is obvious. What is not so obvious is the undoubted fact that as a member of a health committee he has opportunities for studying the underlying causes of all manner of public activities, and—even more illuminating—inactivities. If he has cultivated a sense of humour—and he will not be a real doctor if he has not done that—he will find in his work on a town council infinite reason for laughter, and if he can succeed in making the lay brethren laugh with him he will have done more than justify his retention of his seat.

* * *

On the bench his opportunities are even greater. Knowledge of men and women, understanding of

the infinite twists and turns of human behaviour, are needed in the courts more, perhaps, than any where else. Why, the man on the bench must be asking all the time, did that fellow in the dock behave as apparently he did? Why? That must be the keynote all through. And—I say this advisedly, and with a due sense of responsibility—that keynote seems very often to be muffled. The fact of some act contrary to public order is established: the reason for that act is not. That is where we come in, or should come in. Our training and our experience have caused us to look, almost instinctively, for causes. We know that without some understanding of the cause no problem of our professional life can be fully solved: that treatment under such a condition can be no more than empirical. So is it with the problems of the courts. And that is of the very first importance when we are dealing with the problems of the juvenile courts. Children do the oddest things which get them into trouble with the police. Why? It should be our job to find out if we can. It is not easy. Often it is extremely difficult. However, if our good fortune gives us a seat in a juvenile court we shall have plenty of opportunities for trying. Those courts, as established now, provide facilities, freed from all red tape fetters, for making any investigation that may seem advisable.

* * *

Our training and experience should render us peculiarly fitted for work in the courts. We know the people of our district better, perhaps, than any body else. We are familiar with the language called by the police "obscene." It is really no more than ugly and lacking originality: the coarse back chat of a rough fellow stirred by (not infrequently alcoholic) emotion. It is not easy to persuade our lay brethren of the bench to appreciate that. We know how easily back street tempers get stirred by the bare fact that back street people see too much of one another, living as they do almost in one another's pockets. We understand the bitterness lying dormant, and often not so very dormant, in a yard common to three or four little houses. We know something of the back street pride that is so very easily wounded. All these are features that bring people to the defendant's pen in what is called, quite improperly, the police court. If we will, and if our luck has given us a seat on the bench, we may do much in the way of interpreting behaviour that seems, at the first glance, very odd.

* * *

"They shall not understand the sentence of judgment."

Ben Sira wrote that a very long time ago, and he did not mean by it quite what it may seem to mean to-day. But it is as true to-day as when he wrote it. "They" very often do not understand. How should they? The sentence so often is quite incomprehensible to the sentenced. A fine of a couple of pounds, to be levied from a man whose income already is inadequate, means that he and his family will have to go short of vital necessities. A sentence of fourteen days' imprisonment, with the consequent "sack," means—what does it mean? We, whose working life has taken us in and out of little houses, visualise at once the problems raised by action in the courts. If we have the will we become vocal.

about them. That does not make us popular in our immediate circle but should we play for that sort of popularity? * * *

In practice a doctor who takes part in public life is likely to find it all rather difficult. He knows too much. That is a very decided handicap—in the eyes of other people. On the health committee he will be in immediate conflict with those who own or are friends of those who own insanitary property. On the bench he will be in conflict with those who have an itch for punishing and no desire whatsoever for understanding. He is not unlikely to find his path very thorny indeed. But if he be dogged—and what real Taddygaddy is not dogged?—he will win. For there are those who will heed if only he express himself with sufficient force.

Why is it that so few of us relatively take part in public life? I think it is because we are like miners content to be a class apart. Miners shelter in ugly dwellings remote from other people. We shelter behind brass plates and surgery lamps. While actually as sociable as any other men in our working time we assume a sort of esoteric aloofness and most unfortunately many of us carry our working habits into our play time. I suppose we are, in a way, shy. Also there is this undoubted fact to be faced—a doctor must not take sides on any subject too fervently if he is to make good at his main job. His day-to-day work brings him into contact with all sorts, and he does not wish to offend any. That is reasonable, but it does in practice mean that a great deal of potentially valuable public activity is allowed to run to waste.

CORRESPONDENCE

ANÆMIA AND THE PITUITARY

To the Editor of THE LANCET

SIR,—We have read the annotation on p. 877 of your last issue with considerable interest but we should like to point out that it does not give a very clear view of the position. This is, we suggest, as follows—

(1) We published in 1934^{1,2} a series of papers describing the appearance of a gastric lesion in the rabbit and other animals following the injection of posterior lobe extracts. This has been confirmed by a large number of workers.³⁻⁶

(2) We have also shown that small doses of pituitary extract will inhibit gastric secretion.⁷

(3) We showed that the injection of posterior lobe extract into the rabbit will cause in about 20 per cent of the animals a very severe macrocytic anaemia and since this was associated with reticulo-endothelial and with excessive production of bile we were led to make the following comment: The interpretation of these results is at present obscure. The possibility arises that the control of blood destruction by the reticulo-endothelial system may be vested outside the system itself and may reside in the posterior lobe of the pituitary gland.⁸

(4) Gilman and Goodman in a series of papers⁹⁻¹¹ have repeated these observations and have fully confirmed the fact that the injection of posterior lobe extract into rabbits will produce an anaemia of exactly the same type as that described by us. They however advance a different explanation from the very tentative suggestion put forward by ourselves. We shall in the near future produce further evidence on this point.

(5) The paper referred to by your annotator by McFarlane and McPhail,¹² again confirms our findings using guinea pigs. These workers demonstrate the development of anaemia in guinea pigs following the injection of posterior lobe extracts. They killed their animals at a date so long after the injection that the stomach lesion that would have been present would undoubtedly have been healed. It is interesting to note also that these workers found that the anaemia did not come on in the guinea pig until so late a date after the injection as to render the explanation advanced by Gilman and Goodman extremely unlikely.

Our object in writing this letter is to point out that in all these papers there is no question of the validity of the fundamental observation that a severe

anaemia may be produced by the injection of pituitary extracts.

We are Sir yours faithfully

THE TAVISTOCK CLINIC

To the Editor of THE LANCET

SIR,—The council of the Institute of Medical Psychology have decided after much deliberation to change its title and revert to the original name of The Tavistock Clinic. I should like through your columns to notify the profession of this fact so that no confusion may arise in their minds.

The Tavistock Clinic was the original name adopted when in 1920 the work of providing psychological treatment was begun in a house in Tavistock square. As the clinic grew its name became well known amongst the profession at home and also on the Continent and in the United States. A good many people seem hardly to have realised that it was changed some four or five years ago and to them there will seem nothing unusual in our new title.

The change has seemed advisable largely because of the constant confusion which arose as a result of the non-medical institutes of psychology and psychotherapy which have arisen during the past few years. Some of these have gone so far as to copy our literature and our stationery, evidently feeling that this was likely to be of value to them. Any hospital is reluctant to change its name because there is inevitably some loss of goodwill particularly amongst those who support or might support the work. I am confident however that we can rely upon our many friends in the profession to see that such a loss does not occur and that whatever good reputation the Institute of Medical Psychology had shall be

[APRIL 17, 1937]

carried over to the Tavistock Clinic which certainly needs all the help that they can give it
I am, Sir, yours faithfully,
HENRY B BRACKENBURY,
Chairman of the Council
London W C 1, April 12th

The Tavistock Clinic Malet place

MEDICAL EDUCATION OF WOMEN

To the Editor of THE LANCET

SIR,—Medical women will have welcomed the sympathetic letter from the regius professor of physic at Cambridge in the *Daily Telegraph* of March 25th, in which he supports a plea made by a group of Cambridge women students for more educational facilities in London. I doubt, however, whether his suggestion that the big London schools should admit women, and thereby win the applause of the multitude by a "generous gesture," will tempt them to act against their feelings and possibly their judgment. Medical education is a practical issue, and its development depends on expediency as well as lawfulness. I remember that four London schools admitted women during the war when fees were scanty, and excluded them again when male students became more numerous.

I do not think it is necessary, or desirable, to hammer at unwilling London hospitals, and the Cambridge students little know what they are in for if they should obtain concessions by that means. Women are probably better off even in a second-rate school without prejudice, than in a first-rate school where they are unwelcome.

The opposition of the London hospitals is not altogether without reason. It is said, for instance, that the success of the medical schools depends to some extent upon athletic prestige, and we are assured that athletes hate to be educated with women. It is hardly to be expected that the authorities should forego a clientele they want, for a clientele they don't want. There is another objection, one which may have a wider appeal. In the choice of students a medical school is guided by the return it is likely to get from them—either intellectual or commercial. Compared with men, there is said to be a greater risk of a woman failing to finish the course and still more risk of her failing to practise her profession. The survey of the fate of women medical students educated at St. Mary's between 1916 and 1924 (*Lancet*, 1930, 2, 1370) is of interest in this connexion. Popular medical schools may consider it wasteful to take this chance when they can avoid it. The commercial return from women is also likely to be less valuable because their practices are not usually so lucrative either to themselves or to the consultants.

All this need not unduly depress us. The time will surely come when St. Bartholomew's, St. Thomas's, and Guy's (I quote the hospitals mentioned by Prof. Ryle) will realise that a superior woman may be worth more to them than an inferior man, and in this connexion, also, the report mentioned above is illuminating. Meanwhile the larger non-teaching hospitals, such as the West London and the Royal Northern, might find it a positive advantage to take women as students. Neither is London the only centre of learning, there must be nearly a dozen other universities which provide good medical education. Oxford and Cambridge strike one as being obviously suited to provide the clinical work for modern hospitals, fully staffed and equipped with numerous professors and research departments. It should be understood that no plan for extending medical education is going to be the slightest use to

women unless it includes giving them resident hospital appointments. Openings in hospitals are a far more pressing need than openings in medical schools, and it is misleading, to say the least of it, if a medical school offers equality of education when the hospital connected with it excludes women from competing for the resident posts after graduation.

I am, Sir, yours faithfully,
NORAH H SCHUSTER.

Upper Harley street, N W, April 7th

ERGOTAMINE TARTRATE IN MIGRAINE

To the Editor of THE LANCET

SIR,—I can confirm the experience of your correspondents on the value of ergotamine tartrate in the treatment of migraine. I have been subject to attacks of migraine for 63 years. During the last 40 years I have tried every diet and tested every drug that anyone could suggest. I have seen every consultant in London of whom I heard as having a special knowledge of migraine and have had various injections but all without avail. Twelve months ago I began using ergotamine tartrate in the form of Femergin tablets and it is the first remedy with any prophylactic effect which I have taken. In my case it has been more the severity than the frequency of the attacks which it has influenced. I have been taking two tablets every night now for over a year without any ill effect except that for a couple of weeks at first there was a daily attack of slight intestinal colic for about two hours. When I began the treatment I was spending a day in bed every ten days but the interval at once lengthened to three months. The intervals of freedom from headache during the continuance of the pain must of course continue. No doubt with injections the relief would have been still more marked.

I am, Sir, yours faithfully,
J H CROWLEY
Jersey C I, April 9th

PRECIPITATE LABOUR

To the Editor of THE LANCET

SIR,—Some of your readers may be interested in the following case—

A European primipara aged 28, healthy except for a mild degree of glycosuria controlled without insulin by ten lines of R. D. Lawrence's diet, went into labour at full term on the night of July 29th, 1936, at 11 10 P.M. The pains were slight and only amounted to abdominal discomfort but, merely as a precaution, she called the nurse at 11 30 P.M. At 11 40 she had the first real pain and this was followed by another which ruptured the membranes and produced the infant at 11 45 P.M., much to the dismay of the nurse who had naturally not anticipated such rapid developments and had made no attempt to control the passage of the head over the perineum. The placenta followed the infant within three minutes and examination of the patient on my arrival at midnight revealed a complete tear of the perineum and from 1½ to 2 in. of the rectum. The infant weighed 6½ lb and the whole duration of labour from the first premonitory signs until the delivery of the placenta was less than 40 minutes.

Immediate suture of the torn perineum and rectum resulted in an uneventful convalescence.

The two questions suggested by this case are, first, whether the glycosuria had any connexion with the precipitate labour and, secondly, why nature in such a case did not provide for the preservation of at least the rectal sphincters.

COLLECTIVE AUSCULTATION AND THE REGISTRATION OF HEART SOUNDS

To the Editor of THE LANCET

SIR,—Dr Vaughan Henriques's interesting paper in your issue of March 20th leads me to give you an account of my own researches. With the help of my assistant, Mr G Minot engineer E.P.C.I. an apparatus has been invented which makes it possible (1) to reproduce by loud-speaker the murmurs and sounds of the heart, and (2) to register on films and records the sound vibrations heard in the loud speaker. Our instrument which was standardised by the firm Petit (Ezanville, Seine-et-Oise France) has been in use for two years in my service at the Tenon Hospital in Paris. It was shown at the International Cours Tomarkin in Spa (Belgium) in September 1935 to the Société des Médecins des Hôpitaux de Paris on May 15th 1936 and to the Société de Biologie on May 16th 1936. It is made in three parts: the *telestethophone* for collective auscultation, the *phonostethograph* for registering the sounds on films, and the *medical pick up* for registration of sounds on records and their subsequent reproduction. It has been made especially for the heart, but we have made use of it also for the arteries, lungs, and abdomen.

The *telestethophone* includes a microphone an amplifier and a loud speaker. The microphone is intended to catch and transform into electric waves the audible vibrations of the chest wall. Its special structure renders it insensitive to the infrasonic vibrations of this coat and also the vibrations of the air. For this last reason the sounds diffused by the loud-speaker have no influence on the microphone; it is therefore quite possible to speak near the patient without interfering with the clearness of the auscultation and to place him near the loud speaker without any screen in between. The amplifier is regulated so as to amplify the electric oscillations the frequencies of which are included in the audible scale of the auscultation phenomena (20 to 800 periods a second). It is placed in a metal portable box 20 in. long by 10 in. wide by 12 in. high. The *telestethophone* has neither dry battery nor

accumulator and is connected to the main. To make it work one needs only to press two knobs: one of which regulates the intensity, the other the tone.

The *phonostethograph* is included in the box of the *telestethophone*. It consists of a special oscillograph joined to the loud-speaker and permitting the registration of the vibrations on a film as they are heard. This apparatus has also been made without a loud speaker but with one or two head phones for hearing. The sensitiveness of the normal ear varies greatly according to the frequency of vibrations and the oscillograph has been regulated so that its sensitive ness resembles that of the ear for vibrations of 20 to 800 periods a second. The reproduction of heart sounds (phonocardiogram) is thus rendered as exact as possible and its interpretation is made easier by the simultaneous registration for example of the electrocardiogram on the same film. A tracing with notches (*en dents de scie*) can also be made.

The *medical pick up* allows us to engrave on a record the cardiac sounds and murmurs heard in the loud-speaker or ear phones of the *telestethophone*. A special little apparatus allows us also to engrave on the record oral explanations of the sounds heard. The *medical pick up* when used alone gives faithful reproduction by loud-speaker of the sounds registered. A special process of registration and of reproduction enables us to eliminate the noise of the friction of needles. Records of the auscultation of the heart (*stethodiscs*) are being prepared for issue.

This instrument is useful for teaching because it enables a whole class of students to hear a patient's heart or the records made from auscultation. It is also of value at medical meetings for the presentation of interesting cases. From a practical point of view it enables us to follow the sounds and murmurs of the heart at various periods of an illness and leaves us documentary evidence of previous conditions. Thus in Paris it has been adopted by the Ministry of Pensions. Lastly from a scientific point of view the study of films is rich in new ideas.

I am Sir yours faithfully

C LIAU

Professeur Agrégé in the Medical Faculty of Paris and Physician to the Paris Tenon Hospital.

Paris April 4th

OBITUARY

FREDERICK STAPLETON DICKEY HOGG

M.R.C.S. Eng. L.R.C.P. Lond.

WE regret to learn of the death of Dr Frederick Hogg for 35 years medical superintendent of the Dalrymple Home for Inebriates Rickmansworth which occurred at a nursing home at Brighton on April 5th.

The elder son of the late Sir Frederick Hogg, Director General of the Post Office of India, he was educated at Repton and Jesus College Cambridge and went for his medical training to St. George's Hospital. His career at the hospital was broken by an interval of some three or four years during which he was engaged in sheep farming in Australia, but on his return to the hospital he took the English double qualifications in 1888. He held appointments at the West London Hospital and the Ear, Nose and Throat Hospital after which he went to India in the service of the Bengal Nagpur Railway. At the expiration of his appointment as chief medical officer to the railway he returned to England and entered for a short time into a partnership in north London. His wife's health led him to leave London and take a practice in Southwester and

while there he was elected medical superintendent to the Dalrymple Home for Inebriates Rickmansworth. This position he occupied for 35 years until the institution was wound up under the conditions of its foundation. At the Dalrymple Home he made a name for himself in the treatment of inebriety. His management of the patients was sympathetic and remarkably successful while his notes on drug habits were the result of careful and ingenious attention many of his experiments on the effects of the remedies employed and their dosage and periods of administration being attended with success often of a permanent nature. He took his patients into his confidence and made them the intelligent assistants of their own treatment, inviting them also to keep in regular touch with him especially through their own doctors. He was asked on many occasions to record his experiences but always seemed unwilling to do so, the one exception being the article on drug habits in Quain's Dictionary of Medicine. But the practical nature of his insight into inebriety was known to many colleagues who consulted him and was often of valuable assistance to THE LANCET.

Dr Hogg had lived in retirement at Brighton for the last three years, a cardiac condition entailing upon him a very quiet life. His devotion to the interests of his patients in a residential institution which he never seemed free to leave led to the making of few personal friends, but to those who knew him his simple and generous nature as well as his all round knowledge of his work made a strong appeal. He had been a widower for some years and leaves one son.

FRANCIS GARLAND COLLINS, M.R.C.S. Eng D.P.H.

Dr Francis Collins, medical officer of health for West Ham, who died on March 30th, was a distinguished public servant. He received his medical education at University College, London, and the London Hospital and took the English double qualification in 1907. After serving as house physician to the London Hospital he was appointed assistant medical officer to the Whipp's Cross Infirmary and from that time his whole professional life was spent in municipal medical work. He was appointed assistant medical officer, becoming later senior resident medical officer at the Plaistow Fever Hospital and was tuberculosis officer at West Ham when he took a commission in the R.A.M.C. He saw service throughout the war, first at home and then in Serbia and with the army at Salonika. He returned to his duties as tuberculosis medical officer, and in 1924 was appointed medical officer of health for West Ham, a position which he held at the time of his death. He earned golden opinions by his work, paying special regard to maternity and child welfare, while the reduction in the maternal mortality-rate in the district under his supervision was remarkable enough to obtain special comment in the House of Commons from the Minister of Health.

Dr Collins made communications to THE LANCET of a valuable character. In 1920 he related the after history of 570 tuberculosis dispensary cases, being at that time medical adviser to the West Ham insurance committee. He gave facts and tabular statements in support of the views that it is seldom that any but early cases derive permanent benefit from sanatorium treatment, and that much more strenuous preventive measures should be adopted, such as the foundation of additional suitable open-air schools and institutions for very advanced cases. He collaborated with Dr Helen Campbell, then assistant medical officer for maternity and child welfare at West Ham, in reporting a series of cases of pemphigus neonatorum in which the practical conclusions were arrived at that any midwife or doctor who had been in contact with a case should not attend another confinement until after thorough disinfection of both person and belongings, adding that the disease should be made notifiable.

Dr Collins had been in bad health for a long period, the result of dysentery incurred during his war services, and for the last five months of his life he was confined to bed. He was only 55 years of age at the time of his death.

CÉCILE BOOYSEN, M.R.C.S. Eng

THERE are very many who have learned with regret of the death on April 7th of Dr Cécile Booyesen. This occurred after an illness of five weeks' duration at the age of 42. Her career was that of a woman of outstanding vigour and strong personality. She was the daughter of a South African farmer who, having determined to become a doctor, borrowed the money

necessary for her medical education. After attending classes at King's College, she went for clinical training to Charing Cross Hospital and in 1926 obtained the English double qualification. She served as house surgeon at Charing Cross Hospital and acted also as clinical assistant at the Paddington Green Hospital for Children. She then went into practice in north London and in 1935 founded a voluntary birth control clinic, the Goswell Women's Welfare Centre, in a very poor and overcrowded district. Her environment as well as her natural impulses led to a deep interest in politics, which manifested itself in her support of the labour policy. The horrors of war made a strong impression upon her, and after attending the Brussels Peace Conference in 1936 she started and worked actively for the Medical Peace Campaign where she acted as honorary secretary.

Prof J. A. Ryle writes: "The news of Dr Cécile Booyesen's death will have brought grief and distress to all who knew her. Among the many able women doctors in London, she belonged to a group and a generation which stands particularly high in my estimation, and established unobtrusively a position which will cause her to be long remembered and revered. It was a privilege to meet her in consultation and to observe the care and thought and consideration which she devoted to her patients and which in turn earned their evident devotion to her. She was the organising secretary and inspiration of the Medical Peace Campaign in this country, and in her conduct of its affairs she must have expended a great deal of the energies of her later months. Whatever success attends this movement in the years to come—and it must be recognised as one of the first serious attempts to investigate the psychological causes and consequences of war, and to study and anticipate the medical problems associated with war—a very great measure of that success must be attributed to her self-imposed task. That task had for its goal the better and safer world for which we all hope but few so assiduously strive."

RICHARD WHITTINGTON, M.D. Oxon

Dr Richard Whittington, whose death occurred at Hove on March 30th, was educated at King's College, London, and Merton College, Oxford, proceeding for his medical training to St Thomas's Hospital. He took honours in the natural sciences tripos at Oxford and graduated as M.B., B.Ch. in 1898, proceeding to the M.D. degree at a short interval. At his hospital he held for a time an appointment in the skin department and was later resident medical officer at the Royal Free Hospital, and house physician and pathologist at the Sussex County Hospital, Brighton. He acted for a time as surgeon to the Second African Field Force and recorded his experiences in a paper in *Treatment* entitled "Prophylactic Measures against Enteric Fever in Armies." He settled in practice in Brighton over thirty years ago and became prominent alike as practitioner and public worker. He was an active member of the British Medical Association, holding the post of chairman of the Brighton division, and being a representative at the recent annual meeting at Oxford. During the war he served on the staff of the 2nd Eastern General Hospital which was officered by the R.A.M.C.

Dr Whittington will be long remembered in the borough for his public work. He was a member of the old Brighton board of guardians and served on the education committee of which he was chair-

man He was for twelve years a member of the Hove town council, and served continuously on the East Sussex council of which body he was at the time of his death an alderman He was on the directing bodies of the Brighton, Hove, and Sussex Grammar School, the Brighton Technical College and School of Art and the Hove County School for Girls The conscientiousness with which he performed all his public duties was illustrated by the record of his attendances for during the year 1935-36 out of 162 summonses to meetings by the Hove town council and the Hove education committee, he attended 138 times During the last year of his life he suffered from cardiac symptoms which made of this energy a remarkable record of devotion to duty

Dr Whittington married a daughter of the late Mr E L J Ridsdale of Rottingdean a sister of Mrs Stanley Baldwin. She predeceased him leaving one daughter who was a frequent companion of her father at social functions where official positions made his presence necessary

THE LATE PROF C C CHOYCE

Dr Arthur Davies writes: So deeply do we revere the memory of Charles Coley Choyce at the Seamen's Hospital that it would be a dereliction of duty not to support the appreciations of his worth that have been so well expressed by his friends at University College Hospital. Coming to us as house surgeon to Mr William Turner in 1902 he returned in 1905 as medical superintendent succeeding Mr Johnson Smith who had held that post with great distinction for over 40 years His appointment coincided with a change of policy as regards the staffing of the hospital and this was effected with characteristic courtesy by Choyce who always referred to his predecessor as that great gentleman J S In 1907 he was appointed assistant surgeon and became teacher in operative surgery worthily upholding the high traditions that had been established at the Seamen's Hospital. In the same year he was

selected to shoulder another heavy responsibility being appointed Dean of the London School of Clinical Medicine, an adventurous essay into post graduate teaching undertaken by the staff of the Seamen's Hospital and by extramural lecturers of eminence The daily task of coördinating the activities of such an unparalleled combination of teachers was successfully carried out by Choyce notwithstanding the constant difficulties of finding adequate material suitable for clinical demonstrations. The fierce protests made by the teaching staff rightly importunate for such material were met with equanimity and serenity and peace was marvellously conserved as none misdoubted his motives none his absolute integrity It was at this period that Sir Malcolm Morris, one of the post graduate teachers selected Choyce as editor of the now famous System of Surgery and again a difficult task was carried through with conspicuous success At that time Choyce was a young and relatively junior surgeon and it was not easy for him to coördinate the strong individualistic opinions of his distinguished contributors nevertheless his editorial blue pencil prevailed. During this period began his friendship with Mr Gwynne Williams and their daily discussions on current surgical practice were a happy blend of pungency and good humour Little did either think that this friendship was to be consummated at a later date in common service to University College Hospital. In 1912 Choyce became senior surgeon and in 1919 consulting surgeon to the Seamen's Hospital. Associating ourselves with all that has been so well written of him we would recall how often it fell to Choyce to undertake tasks that were arduous and extremely difficult and how consistently he succeeded. At all times and in all places he was unchangeably himself in loco parentis to all and sundry serene, vallant and wise Our thoughts go out to his father in New Zealand and to his wife to whom we owe our especial gratitude for his comradeship vouchsafed to us and which is now our precious heritage.

PARLIAMENTARY INTELLIGENCE

PHYSICAL TRAINING AND RECREATION BILL

In the House of Commons on April 7th Mr OLIVER STANLEY President of the Board of Education moved the second reading of the Physical Training and Recreation Bill He said that Clause 1 of the measure gave statutory authority to the National Advisory Council which had been at work since March 1st Clause 2 provided for a scheme of local committees whose membership would be like that of the National Council—invited to serve as individuals rather than nominated as representatives of different bodies. Those committees would be charged with propaganda and with seeing that the scheme and its possibilities were brought home to the locality and would examine applications from voluntary bodies for assistance from the Government. All such applications would be submitted by them to the Grants Committee which was dealt with in Clause 3 Sir Henry Pelham would be chairman of the committee Clause 4 was a machinery clause which dealt with the powers of local authorities. The most important new power was that given to a local authority to provide throughout the area that sort of community centre which at the present moment a housing authority could provide on its own housing estate but which the local authority was not able to provide anywhere else Clause 5 dealt with the compulsory purchase of land and Clause 6 remedied the difficulty under the Education Act which enacted that if the local education authority

provided certain facilities for social recreation and physical training they had unlimited powers for children under 16 but powers in regard to those above that age only if they attended educational institutions. The same powers would now exist in regard to those above 18 as in the case of the younger children Clause 7 dealt with the setting up of the national college The whole scheme was now ready for submission to the National Advisory Council He still heard criticisms that this scheme was militaristic but the leaders in the physical health movement on the Continent had not been in the past and were not now Germany and Italy but Sweden Czechoslovakia the democratic popular States, and he thought that we could draw valuable lessons from the systems adopted in those countries Those systems had no element of compulsion and were not applicable as a whole for it was not wanted to substitute physical training for games but to supplement games by physical training The keep fit slogan was one of the best ever invented What was not so widely known was the remedial effect that physical training could have and that wise training given under proper instruction, and with a scientific basis could do much to remedy some of those minor and indeed some of the major ills to which a highly civilised and industrialised society was liable

Attempts had been made to found arguments against this scheme upon a nutritional basis, but this was an entire mistake The machinery necessary

to ensure that the school child should come to physical training with a well nourished body was in existence, and if it was properly used there should be no malnutrition in our schools. He was determined that that machinery should be used, and he appealed to all hon. Members to help him in impressing the importance of this machinery on local education authorities in their areas, and in inducing them to put it into the fullest possible operation. He would remind the House that the recent block grant made available largely increased sums to the local authorities on which services of this kind might well have the first call. Anyone who read the First Report of the Advisory Committee on Nutrition would gather from its whole tenor that the picture of a nation in general suffering from malnutrition was a false one. The committee laid stress on the possibility of extending the consumption of milk both in the schools and afterwards. That report would, of course, receive careful consideration from the Government. It was a difficult and not wholly an economic problem. It was not just a question of the price of the product and the pocket of the purchaser, but a question of taste, of belief in it, and although a child could lead a man to a milk bar a whole Cabinet could not make him drink.

This was a scheme not only for physical training, but also for recreation. It was part of a problem just as important, namely, the use of leisure. Leisure was to be different not only in content, but in quality from anything that the general masses of the people had experienced up to now. It was going to be regular and not spasmodic. What use were we going to make of such leisure? He was quite certain that regular leisure of the kind he mentioned would demand some more active occupation than just sitting about and resting. The real use of leisure would call for the development of interest, taste and knowledge. Physical recreation, vigorous games, physical training, and hiking would form an important part of any right use of leisure, but it could not be all. He did not believe that physical activity alone was over going to be wholly satisfactory, but the facilities provided for in this Bill might well lead to the development of other and wider interests.

Mr LEES SMITH thought there was a great deal of exaggeration in the belief that strenuous physical exercises up to about 25 years of age would guarantee health for the rest of a long life. Lord Dawson, in a letter to the *Times* a few days ago, had pointed out that he had seen a group of territorials marching out that they had very selected men—and he carefully noted them and came to the conclusion that 50 per cent of them were suffering from physical defects which mere exercises would not remedy, and which would take a heavy toll in later life. Lord Dawson, was one of the two medical members of the committee controlling the scheme, and he wished there had been more of remedial exercises, but the development of open air recreation, differing in type from violent physical exercises.

A matter which was quite definitely at issue between the two sides of the House was the connexion between this scheme and the problem of nutrition. He knew that the Board of Education had issued figures showing that the number of children in which nutrition was apparently bad, and who would come under the scheme, was 0.7 per cent. He did not think that the record of the Board of Education on this question of the proportion of children suffering from malnutrition was a very reliable one. The figures were based upon the impression made on medical officers of health by looking at children. It was clear that the standard at children was that to which he was accustomed in the neighbourhood in which the school was situated. According to that standard—if they took it as a standard—they got the figure of 0.7 per cent with bad nutrition, and 74 per cent who were normal. The whole basis of attempting to judge this problem by the method of looking at the

children in front of them, and asking whether they were up to the average of the neighbourhood, was entirely unscientific and was now being condemned. Mr STANLEY. When the right hon. gentleman says that the method is now being condemned, may I point out to him that the Nutrition Advisory Committee say that the method of the Board of Education is the most promising?

Mr LEES SMITH said that the committee added that the trial had not been sufficiently prolonged to establish its reliability and the method was not reliable. There was another method which scientists said gave results—viz., the calculation of the number of proteins, calories, and vitamins required for physical efficiency at different ages. Then one calculated what it cost, taking the average over a group of people, to buy sufficient food to provide the minimum essentials of those elements. Then one calculated what proportion of the people of this country were buying that food and could afford to buy it. Those were the methods which were being followed up by the Committee on Nutrition, which had not yet reached a final conclusion as to what percentage of the population, judged by this method, would be found to be suffering from malnutrition, but individual members had reached their own conclusion. They could take either of the two limits, the report of the British Medical Association, which stated that 30 per cent of the school population were suffering from malnutrition, as against the 0.7 per cent of this report, or the report of Sir John Orr, who was a member of the committee, and who had come to the conclusion that the optimum diet was absent from 50 per cent of the school-children. The most valuable part of the Government scheme would undoubtedly be that it would force open the whole issue of the standard of living of the people of this country.

Sir FRANCIS ACLAND said he welcomed the Bill. Undoubtedly it was a move in the right direction, and would do great good. But he was sure that the campaign which it would be necessary to have behind this Bill to ensure better physical training and recreation would have gone better in that House if it were being more visibly connected with, and accompanied by, a preliminary campaign for better nutrition.

Viscountess ASTOR said she begged the Government when considering the question of physical fitness to bear in mind that there was no other way that they could get the children properly trained, fed and matured except by beginning before they got into school. No child under 18 ought to work more than 40 hours per week. If they attended to that they might in time get a really A 1 nation to that they might in time get a really A 1 nation.

Mr EDE said that the nursery school had its place, but they must be very careful to see that it was not made an excuse for bad social conditions.

After further debate,

Mr SHAKESPEARE, Parliamentary Secretary to the Board of Education, said that his right hon. friend had every reason to be gratified at the reception given to the Bill by members of all parties. The Government had appointed a body of experts on nutrition who he hoped would educate the layman in the course of time.

It was moonshine to conceive that the people, who might come under this Bill—that was to say, some 14,000,000 persons between the ages of 14 and 35—were so enfeebled by lack of nourishment that they could not stand up, let alone take any recreation. Mr LEES SMITH, he thought, had rather confused two things—the assessment of the nutritional state and the means to be taken to overcome any deficiency in the nutritional state. Although the present system of assessing nutrition was not foolproof, it was the best yet devised, and indeed the experts said that it was the best at present known. He assumed that the right hon. gentleman that if research would find a better one—and he believed that the League of Nations was trying to find a better one—the Government would consider it with a view to adopting it.

The Bill was read a second time and the financial resolution in connexion with it was agreed to in Committee.

EXTENSION OF CONTRIBUTORY PENSIONS SCHEME

In the House of Commons on April 8th Sir KINGSLEY WOOD, Minister of Health, moved the second reading of the Widows, Orphans and Old Age Contributory Pensions (Voluntary Contributors) Bill. He said that the measure would concern at least 2,000,000 persons enabling them to participate in the benefits of the Widows, Orphans and Old Age Contributory Pensions Act on a voluntary basis. Persons who had received these benefits were broadly speaking those who were already compulsorily insured under the National Health Insurance Act or who having once been insurably employed had elected to become voluntary contributors. There had been one considerable gap in the provisions of the principal Act. There had been persistent requests from a section of the community, many of whom paid to provide for others this protection which they needed just as much themselves. Our scheme of social insurance considerable and extensive as it was, could not be regarded as complete so long as persons with small means but not themselves insurably employed were unable to share in its benefits. This Bill had been popularly called The Black-coated Workers Bill. That did not by any means adequately describe its scope. It would be almost impossible even if it were desirable to make a scheme of this kind compulsory because experience had shown that compulsory contributions could be successfully collected only when linked with the payment of wages. It was essential that if the scheme was not to be unfair between applicants and not indefinitely expensive to the taxpayer they must lay down two broad principles. In the first place contributions in a scheme of this kind should increase with the age of entrants and as there was to be no medical examination whatever there must be a substantial waiting period before benefits were payable. They had been able to make provision for continuance in insurance even when full contributions had not been paid and for maintaining the insurance of a contributor who was unable to pay contributions owing to protracted illness which prevented him from earning a living. The Bill permitted of entrance within a year of the inception of the scheme at a favourable flat rate subject to a maximum age limit of 55. The great majority of the men who entered would be married and many of them would be getting on in years. The scheme would naturally be most attractive to them but the insurances provided for in the scheme were mainly for the benefit of women. Its chief attraction for men would be that it enabled them to make provision for widows and children in the event of premature death and he would point out that of the 1s 3d asked for under the scheme nearly a shilling was apportioned for making provision for the wife, widow or children. The Government Actuary put the number of unmarried women of middle age at 500,000 who would satisfy the conditions of eligibility in the first year of the scheme. The difference between the £100 a year income limit for men and the £250 a year income limit for women was not one of sex differentiation at all. It had relation to the responsibilities of the burdens that had to be carried. The greater part of the man's risk was the security of his wife in her old age or his widow and children in the event of his premature death and there was no such cover available for him in any insurance institution on any terms that he could afford. Under this scheme the Government gave adequate benefit and security according to needs, circumstances, burdens and responsibilities in a fair and proper way. As far as the State contribution and help was concerned if anything it erred in favour of women rather than men. He could promise the House that he would

examine the precise terms of the measure when it reached the Committee stage but he commended it to the House as one more measure of British social security and justice and one which he suggested would take a considerable place among social services which were unequalled in the world.

After further debate the Bill was read a second time and the financial resolution in connexion with it was agreed to in Committee.

The financial resolution in connexion with the Physical Training and Recreation Bill was agreed to on report.

THE FACTORIES BILL IN COMMITTEE

The Factories Bill was further considered by a Standing Committee of the House of Commons on April 8th. Major LLOYD GEORGE was in the chair. Examination was begun of Part IV of the measure which deals with special provisions and regulations in relation to health safety and welfare.

Clause 40 (which prescribes that where a process in a factory causes dust or fumes likely to be injurious or offensive measures shall be taken to protect the workers and to prevent the accumulation of dust or fumes in a workroom).

Mr RHYB DAVIES moved an amendment to insert the words "or other impurity." He said that there were other impurities which were altogether outside the description given in the clause.

Mr G. LLOYD, Under-Secretary Home Office, said that on further inquiry the Home Office found that there were impurities which would not strictly be covered by the words in the clause. They were therefore ready to accept the amendment with other necessary consequential alterations.

The amendment was agreed to.

On Clause 47 (which deals with washing facilities and meals in relation to certain dangerous trades).

Sir E. GRAHAM LITTLE moved an amendment to leave out the word "washing" and insert "cleansing." He said he was the only medical man on the Committee and he had received suggestions from expert associations outside Parliament as to what they would desire to put into this Bill. A number of amendments had been put forward by two expert bodies—the Royal Sanitary Institute and the Society of Medical Officers of Health. It had been a common experience with him for patients to show signs of injuries to the skin caused not by the substances with which they had been working but by materials used for washing their hands. Washing was invariably understood as washing with soap and water and the purpose of the amendment was to give a wider choice.

Sir J. SIMON, Home Secretary, did not deny that the point had force but he opposed the insertion of the word "cleansing." The expression "washing facilities" was well known in the industrial code and it was most undesirable to introduce at one point a phrase like "washing and cleansing" and to leave the more familiar expression "washing facilities" in other places. No doubt there were certain soaps containing a chemical ingredient which if brought into contact with the skin of persons suffering from a certain ailment might do more harm than good but that was an argument against washing and they must take a rather broader view. He doubted whether the legal construction which might be put on these additional words would add to the clearness of the law.

Sir F. GRAHAM LITTLE said that he had voiced the opinion of the experts, but in view of what the Home Secretary had said he asked leave to withdraw the amendment.

The amendment was withdrawn.

Mr. SIMON moved an amendment giving the Secretary of State power to prescribe by regulations what in practice was a room in which there was sufficient silicosis dust to be dangerous.

The amendment was agreed to.

Mr RHYS DAVIES moved an amendment which he said was designed to make sure that persons employed in dangerous and injurious processes should not take food or drink in the room where the processes were carried on.

Mr LLOYD said that if the Committee inserted the amendment in the form in which it was moved they would really be making not a reasonable prohibition but an unnecessary restriction. It was essential in regard to the dust which it was poisonous even to swallow, to provide that workers should not stay in the workroom during their rest or meal periods, and also that they should not swallow the smallest particle of food outside their rest or meal periods. With regard to asbestos or silica dust, it was sufficient to provide, however, that they should not remain there during their meal times or rest periods and thus be inhaling the dust.

The amendment was withdrawn, and Clause 47 as amended was ordered to stand part of the Bill.

On Clause 48 (which provides that the Home Secretary may make such special regulations as appeared to him practicable for extending the provision and use in factories in which the weaving of cotton or other cloth is carried on, of shuttles which are not capable of being threaded or readily threaded by suction of the mouth, and any such regulations may impose duties on workers as well as occupiers).

Mr RHYS DAVIES moved an amendment to delete the word "special" in relation to the regulations. He said that the habit of what was called "shuttle kissing" had grown up but now both employers and workers would like to do away with it. The Home Secretary should be able to make regulations to deal with the matter without having to go through all the machinery of inquiry that would be necessary if the regulations were special regulations.

Mr J HERWORTH said that most employers provided apparatus for threading a shuttle, but the difficulty was to get the workers to use it.

Sir J SIMON said it did not appear to have been absolutely proved that "shuttle kissing" caused injurious consequences on such a matter without making regulations. That was the reason why they put in full inquiry. That was the reason why they wanted the words "special regulations" if they could and stop the habit of "shuttle kissing" if they could and he would undertake to take the matter up as soon as the Bill became law for the purpose of making proper inquiries. He promised to look further into the matter.

The amendment was withdrawn and Clause 48 was ordered to stand part of the Bill.

Clause 49 (which provides that no person shall use white phosphorus in the manufacture of matches) and Clause 50 (which deals with humid factories) were both ordered to stand part of the Bill with minor amendments.

On Clause 51 (which provides that no work shall be carried on in any underground room, which is certified by the inspector as unsuitable as regards construction, light, or ventilation, or on any hygienic ground, or where adequate means of escape in case of fire are not provided).

Mr SHORR moved an amendment to make the clause provide that no underground room should be used for work unless it was certified by the inspector to be suitable.

Mr BANFIELD, supporting the amendment, said that an underground room was not a suitable place for processes to be carried on at all. There were hundreds of underground workrooms that ought to be closed, many were absolute rat-holes.

Mr LLOYD said Mr Banfield had referred to underground workrooms which were in the nature of objectionable cellars, but an underground room in the clause meant any room half of which was below the level of the ground. In a number of the luxury flats in the West End of London there were rooms of that kind. The information in the Home Office did not indicate that conditions in regard to

lighting and ventilation were generally bad. On the contrary, a comprehensive inquiry had shown that conditions were much better than might be anticipated and that an improvement had taken place. If the amendment was carried a large number of inspectors would be wanted and there would be a considerable delay in dealing with bad cases.

After further debate, Sir J SIMON said that his advisers took the view, and he did not differ from it, that the clause was in proper form. But he would consider the whole matter again.

The amendment was withdrawn.

On Clause 52 (which provides that a basement bakehouse shall not be used as a bakehouse unless it was lawfully so used at the date of the passing of the Bill into law, and any basement bakehouse which, for a period exceeding 12 months, is not used as a bakehouse shall not be so used again).

Mr BANFIELD moved an amendment to provide that all existing basement bakehouses should not be used after the expiration of five years after the passing of the Bill into law.

After further debate, Sir J SIMON said that the proposal in the amendment had only just come before him. It had never been put forward previously in any of the representations made to the Home Office when the Bill was being drafted. It was their policy to discourage the use of underground bakehouses and he was disposed to share the strong feeling shown about the matter. He could not, however, accept the amendment without having an opportunity of consultation.

Mr BANFIELD agreed to withdraw the amendment, but Mr G BUCHANAN objected, and it was negatived.

The clause was ordered to stand part of the Bill.

Clause 53 relating to the temperature of ironing rooms in laundries and fumes in laundries was also ordered to stand part of the Bill.

The Committee adjourned.

The Factories Bill was further considered by a Standing Committee of the House of Commons on April 18th. Major LLOYD GEORGE was in the chair.

On Clause 54, which provides that a young person shall not be employed to lift, carry, or move any load so heavy as to be likely to cause injury,

Mr RHYS DAVIES moved an amendment to delete the word "young."

Mr LLOYD, Under-Secretary, Home Office, said that regard should be had to a proviso in the clause that empowered the Home Secretary to make special regulations prescribing the maximum weights which might be lifted, carried, or moved by persons employed in factories. That power to make regulations, he said, was regarded as an important way of dealing with special cases and they intended to use that power.

After further debate, Sir JOHN SIMON, Home Secretary, said that the clause was a new one in the Factory Code and was an improvement. There were already regulations to prevent young persons lifting heavy weights, but they could not put into an Act of Parliament some prohibition which was so vague in its terms that it could not be effectively and fairly applied.

The amendment was withdrawn and the clause was ordered to stand part of the Bill.

On Clause 55, which prohibits the employment of female young persons in any part of a factory where the following processes are carried on: melting, or blowing glass, other than lamp blown glass, annealing glass, other than plate or sheet glass, evaporating of brine in open pans or the storing of salt.

Mr W BROMFIELD moved an amendment to include in the prohibition the making or finishing of bricks or tiles not being ornamental tiles.

Sir J SIMON said there was a new sub-clause which gave the Home Secretary power to extend the clause by regulation to any process in which it appeared undesirable that female young persons should be employed, and if he was satisfied that the prohibition

referred to ought not to apply to any of the processes specified or ought to be relaxed he might make regulations accordingly.

The amendment was negatived and the clause was ordered to stand part of the Bill.

On Clause 56 which prohibits the employment of women and young persons in certain processes connected with lead manufacture.

Sir E. GRAHAM LITTLE moved an amendment to exclude women from the prohibition. He said there was no evidence that women were more subject to lead poisoning than men. A discrimination of the kind proposed in the clause would operate against the employment of women.

Viscountess ASTON supported the amendment. Anything that would shut out women from any employment would be resented by them.

The amendment was negatived and the clause was ordered to stand part of the Bill.

Clause 57 which includes provisions in regard to the employment of women and young persons in processes involving the use of lead compounds, was ordered to stand part of the Bill.

Clause 58 (which gives the Home Secretary power to make special regulations for safety and health) Clause 59 (prohibition of importation and sale of articles made with prohibited materials) Clause 60 (power to take samples) Clause 61 (certificates required before approval of building plans relating to cotton cloth factories) Clause 62 (notification of accidents in factories) and Clause 63 (power to extend dangerous occurrences provisions as to notice of accidents) were all ordered to stand part of the Bill.

On Clause 65 which requires notification of certain industrial diseases.

Mr. ELLIS SMITH moved an amendment to delete the list of diseases specified in the clause (lead phosphorus, arsenical or mercurial poisoning or anthrax) and substitute the definition "any industrial disease to which the provisions of Section 48 of the Workmen's Compensation Act 1925 apply or silicosis."

Sir E. GRAHAM LITTLE supported the amendment. Sir J. SIMON opposed it and the amendment was withdrawn.

The Committee adjourned.

NOTES ON CURRENT TOPICS

Voluntary Sterilisation

In the House of Commons on April 13th on the motion that the Speaker do leave the chair on the House going into Committee of Supply on the Civil Estimates.

Wing-Commander JAMES called attention to the need to implement the report of the Committee on Voluntary Sterilisation and moved that, in the opinion of this House the Government should give further consideration to the potentialities of voluntary sterilisation for hereditary defectives in accordance with the unanimous recommendations of the Departmental Committee that reported to the Minister of Health on Jan. 8th, 1934.

Sir KINGSLEY WOOD, Minister of Health replying to the debate which followed said there was no question that opinion in this country was growing in favour of sterilisation but they could not disguise from themselves the fact that opposition remained and that there was still much conflict of opinion particularly on religious grounds. The medical profession were by no means unanimous on the matter. It was desirable that ample time should be given for full consideration of the whole problem and for public opinion to develop as he thought it was developing.

Wing-Commander JAMES said that in view of what the Minister had said he would withdraw his motion.

Mr. ROWSON called attention to the question of nutrition.

Sir KINGSLEY WOOD said that the Ministry of Health Advisory Committee on Nutrition in their most valuable first report said that a good deal of

further information on the facts must be obtained before it was possible to reach a final policy on nutrition. He had asked the authorities to review the scale of income observed in connexion with the requirement for repayment for milk or for food supplies. He had also asked the authorities to consider afresh the question of a properly organised system of meals, and he had reason to believe that the authorities would be able to continue and extend the work they were now doing. The Department would undertake certain dietary surveys which the Advisory Committee recommended. This would take time but would not stop the work now going on.

The motion that the Speaker do leave the chair was carried by 161 votes to 120.

QUESTION TIME

WEDNESDAY APRIL 7TH

Underground Protection against Air Attack

Major STOURTON asked the Home Secretary to what extent underground protection would be made available to the civilian population of London in the event of an air attack.—Mr. GEORGE LLOYD, Under-Secretary, Home Office replied: Where accommodation exists below ground level which can be suitably protected against splinters falling debris and poison gas, the occupiers of premises will be advised to make use of it. As however underground accommodation is rarely proof against a direct hit by a high explosive bomb the overriding consideration in the choice of air-raid refuges must be to keep the population well dispersed in splinter proof and gas-proof accommodation whether it is below or above ground level.

Medical Jurisprudence

Captain ELLISTON asked the Home Secretary whether in accordance with the recommendations of the advisory committee on the scientific investigation of crime it was proposed to establish a medico-legal institute for pathological research and as a training centre for experts in medical jurisprudence.—Sir JOHN SIMON replied: The Committee's report is primarily concerned with measures for improving medical education in certain directions; while I am in sympathy with their recommendations they fall also within the province of the Minister of Health with whom I am in consultation on the matter. My hon. friend will of course appreciate that the Committee's proposals would involve a substantial charge upon the Exchequer.

Medical Research Council and Silicosis

Mr. JAMES GRIFFITHS asked the Lord President of the Council what progress had been made by the Medical Research Council in their investigations into the problem of silicosis and other lung diseases among coal miners; and whether he could give any indication as to when the committee's investigation would be completed.—Mr. RAMSAY MACDONALD replied: The standing committee appointed by the Medical Research Council to direct research into disease of the lungs among industrial workers has already promoted several investigations into silicosis and other conditions; the results have been published in a series of official reports and scientific papers. These researches were in most cases not specially directed to the particular problem of lung disease among coal miners but during recent months attention has been concentrated on this, and a scheme of intensive investigation in South Wales has been initiated. The work already done shows the problem to be one of great difficulty and complexity and the investigation is not likely to be completed in less than two years.

Mr. J. GRIFFITHS said that in view of the unsatisfactory nature of the reply and the position of the men who were affected he would raise the matter at the earliest opportunity.

Hospital Treatment in Staffordshire

Mr. MANDER asked the Minister of Health if he was aware of the great dissatisfaction caused in Wednesfield and Willenhall as a result of the coming into force on

April 1st of the new arrangements for the treatment of invalids, both public assistance applicants and hospital contributors, under the new Staffordshire County Council scheme, if he realised that it was now necessary for patients to be taken a distance of from 8 to 10 miles to Wordsley Institution instead of receiving treatment in the immediate vicinity at the New Cross Hospital of the Wolverhampton Borough Council, and what resident medical officers were available at Wordsley Wood replied that the plans of the Staffordshire County Council for the reorganisation of the hospital and other institutional accommodation in the county include the reconstruction of the present institution at Wordsley as a general hospital to serve the sick in the southern part of the county. The hon. Member will appreciate that the improvement of institutional services and the better classification of patients, which were one of the objects of the Local Government Act of 1929, must sometimes involve the removal of certain patients to a greater distance from their homes but if the hon. Member has any particular cases of hardship in mind I will make inquiries. With regard to the last part of the question, I understand that the medical officer of the Wordsley Institution lives near at hand and is always available, and that the council propose to appoint a resident medical officer or officers as soon as the reconstruction permits.

Overcrowding in Croydon District

Dr SALTER asked the Minister of Health whether he was aware that, despite the serious shortage of accommodation available at rents within the means of the lower paid wage-earners in the Croydon district and the grave overcrowding prevalent in the area, the Corporation of Croydon had made regulations under which an applicant for a municipal house must have resided in the borough for a period of at least 10 years to render such applicant eligible for a dwelling let at a rent of less than £1 per week, and whether such a policy had his approval. Sir KINGSLEY WOOD replied: I understand that the regulations made by the town council include a condition to the effect mentioned, but that this condition is relaxed in the case of overcrowded families, persons displaced by slum clearance and the abatement of overcrowding, and other cases where special circumstances exist. My approval is not required to the regulations made by local authorities for the management of the houses provided by them.

Cost of Living Inquiry into Family Budgets

Mr SANDYS asked the Minister of Health whether it was the intention of the Government to institute the diet recommended by the Advisory Committee on Nutrition in their recent report, in so far as these were not already covered by existing investigations. Sir KINGSLEY WOOD replied: Yes Sir. The dietary surveys have already commenced. As regards family budgets, it is hoped to obtain information as to food consumption by the course of the inquiry which is being undertaken by my right hon. friend, the Minister of Labour for the purpose of the revision of the cost of living index number. The method of carrying out the remaining proposal is receiving immediate consideration.

MONDAY, APRIL 12TH

National Health Insurance Referees

Mr GRAHAM WHITE asked the Minister of Health how many referees had been appointed under Section 90 of the National Health Insurance Act 1924 and the rates of their remuneration. Mr HUDSON, Parliamentary Secretary, Ministry of Health, replied: The number of referees in England and Wales is eight and their remuneration is a fee not exceeding 10 guineas a day or 12 guineas where a hearing extends beyond seven hours.

Supervision of Nursing Homes

Miss RATBORNE asked the Minister of Health (1) whether he would institute an inquiry into nursing homes all over the country in view of the many complaints as to the

inadequate and insufficiently qualified nursing staffs and the insufficient precaution taken in regard to the prevention of infection, and (2) whether he had reason to believe that nursing homes were adequately inspected from the point of view of the sufficiency and qualifications of the nursing staff, and also that adequate care was given to the prevention of infection, particularly when maternity patients were taken in addition to general medical and surgical cases. Mr HUDSON replied: The attention of local authorities has recently been called to the importance of the adequate supervision of nursing homes in a circular letter of Sept 30th last. As at present advised my right hon. friend sees no necessity for a special inquiry, but he will look into any case which the hon. Member may have in mind if she will communicate the particulars to him.

Nursery Schools

Mr LYONS asked the President of the Board of Education the latest progress in the development of nursery schools, and what proposals were in immediate contemplation. Mr GEOFFREY SHAKESPEARE replied: The present position is that 86 nursery schools are recognised for purposes of Education, of which 83 are recognised for Board of Education, and three as efficient but not in receipt of grant. In addition, 34 proposals for new nursery schools have been approved in principle and in a number of these cases final plans have been approved by the Board, and seven proposals are at present under consideration.

TUESDAY, APRIL 13TH

National Health Insurance Drug Fund

Colonel ROPNER asked the Minister of Health whether, in view of the incidence of sickness during the early months of the present year, he proposed to make special provision to ensure that the Drug Fund should be able at the end of the year, to meet in full its liabilities to chemists and bodies corporate dispensing under the National Health Insurance Acts. Mr HUDSON replied: As the Drug Fund relates to the calendar year it would be premature at this stage to estimate the extent, if any, by which payment of the chemists' accounts will be affected by the sickness experience early in the year. My right hon. friend undertook at the time the present agreement with the chemists was made to consider representations regarding any abnormal deficit in the Fund.

Overcrowding in Scotland

Mr MAXTON asked the Secretary of State for Scotland what progress had been made since the passing of the Housing Act, 1935, in combating the problem of overcrowding in Scotland, and in how many places had the appointed day been fixed. Mr ELLIOTT replied: Since the passing of the Housing (Scotland) Act, 1935, tenders have been completed for 36,012 houses and 24,377 houses have been approved for subsidy purposes under either the Act of 1930 or the Act of 1935, but, under arrangements designed to secure that the most economical use is made of the new accommodation they are used for slum clearance or overcrowding purposes as local circumstances or need may dictate. There is no record of the number of families actually removed from overcrowded houses prior to April 1st, 1936, but from that date to Feb 28th, 1937, 6,444 families living in overcrowded conditions were rehoused. The appointed day under the Housing (Scotland) Act 1935, has so far been fixed for only one area, namely, the Dewart Ward of the Burgh of Kirkcaldy. The date fixed in this instance is May 15th, 1937.

INTERNATIONAL CONGRESS OF OPHTHALMOLOGY.—This congress will be held at Cairo from Dec 31st to 15th. Several tours leaving Marseilles on Dec 3rd have been arranged in connexion with it under the auspices of the International Council of Ophthalmology. Visits will be paid to Upper Egypt, Palestine, and Syria. Dr E. Marx of Rotterdam is acting as secretary general of the congress, and further details about the tours may be had from the Bureau des Croisières et Voyages Médicaux, 29, Boulevard Adolphe Max, Brussels.

MEDICAL NEWS

University of London

At a recent examination the following candidates were successful —

D.P.H.

Part I — Beatrix H. Bakerell J. S. B. Bray Enid S. Davies Sylvia G. Gavron E. H. Hartle M. U. Hayat S. M. H. Naqvi A. W. Rashid H. C. Salzena Margaret B. Steel M. A. de S. Suriyawansa and V. M. Vaitro

Sir Ernest Graham Little has been appointed representative of the University at the celebrations to be held on the occasion of the 400th anniversary of the foundation of the University of Lausanne from June 3rd to 5th.

Three lectures on the meninges and the cerebro-spinal fluid will be given on May 24th, 26th, and 28th at University College at 5.30 p.m. by Dr Lewis H. Wood, director of the school of medicine and professor of anatomy in the Johns Hopkins University, Baltimore. Dr J. Henderson Smith, head of the department of plant pathology at Rothamsted experimental station, will speak on virus diseases of plants at 5.30 p.m. at the Imperial College of Science and Technology on May 13th, 20th and 27th. Prof. J. M. Hollborn, F.R.S. Sir Samuel Hell, professor of chemistry and director of the chemical laboratories of the University of Manchester will also lecture there at 5.30 p.m. on May 24th, 25th and 26th. He will speak on the chemistry of the carotenoids and vitamin A. Prof. H. Rein, director of the physiological institute of the University of Göttingen will lecture at University College on May 3rd, 4th and 6th at 5 p.m. His subject will be some economising mechanisms as a condition of the body's adaptation to increased activity. It has also been arranged for Prof. H. Frederick, professor of physiology in the University of Liège to give a lecture at King's College on interpretation of the normal electrocardiogram. The lecture will take place during June and the date will be announced later. The lectures are open without fee to all who are interested.

The following examiners for the diploma in theory and practice of physical education have been appointed —

Anatomy — Dr Doris Baker and Dr Lilian Dickson
Hygiene — Dr Ruth Proctor and Dr James Kerr
Theory of Gymnastics — Dr Anna Broman and Surgeon-Commander G. Murray Levick.

University of Birmingham

On May 18th and 20th, at 4 p.m. Prof. Arvid Wallgren, physician-in-chief to the Children's Hospital at Gothenburg will deliver the Ingleby lectures. The first will be on erythema nodosum and the second on childhood infection and adult type of pulmonary tuberculosis.

From May 24th to June 4th a post-graduate course will be held on the care of the injured workman and from June 14th to 25th there will be an intensive course in industrial hygiene and industrial medicine. Further information may be had from Dr Howard Collier at the department of industrial hygiene and medicine at the University.

Provisional arrangements are being made for a post-graduate course in neurology to be given from May to July in hospitals associated with the University. Further information may be obtained on application to the dean of the faculty of medicine of the University, Edmond street Birmingham 3.

Pathological Research in Relation to Medicine

Our advertisement columns contain particulars of a course of lectures on this subject to be given in the institute of pathology and research at St. Mary's Hospital at 4 p.m. on Tuesdays from April 27th to June 22nd. The first is by Sir Almonroth Wright, F.R.S., principal of the institute and the other speakers will be Dr F. M. R. Waldo, Mr W. T. Thompson, F.R.S., Prof. I. C. Dodds, Mr F. T. Riley, Dr Wilson Smith, Prof. J. A. Gunn, and Dr W. I. Gye. An abstract of each lecture will be found in our advertisement columns the week before its delivery. The lectures are open to all members of the medical profession.

Royal College of Surgeons of England

A meeting of the council was held on April 8th with Sir Cuthbert Wallace the president in the chair. The Jacksonian prize for 1936 was awarded to Mr W. E. Underwood, F.R.C.S. (St. Bartholomew's Hospital). The subject for the Jacksonian prize for 1938 will be surgery of the heart. The John Hunter medal and triennial prize was awarded to Mr L. F. O'Shaughnessy, F.R.C.S. for his research work on the surgery of the thorax.

Mr Ernest Eric Young and Mr Arthur George Wells were elected fellows of the college under the charter which permits the council to elect annually to the fellowship without examination two members of the college of twenty years standing.

It was decided that the post of fourth house surgeon at the Royal Surrey County Hospital Guildford should also be recognised for the six months surgical practice required of candidates for the final examination for the fellowship.

Diplomas of membership were granted to A. E. H. Eades (Univ. of Edin.) to K. C. Royce (Univ. of Oxford and St. Thomas's Hosp.) and to Eric Vernon (Univ. of Manch.). Diplomas in child health were granted jointly with the Royal College of Physicians to the following candidates —

Margaret D. Baber, H. B. Bann, M. L. Blawie, V. S. H. Davies, J. G. H. Frew, J. H. Green, Joyce B. Jewson, Bernard Kruton, A. H. M. Korha, S. K. Lee, U. K. Lim, Louise A. Mathison, Dorothy Miller, A. L. Smallwood, S. F. L. Stenling, Elizabeth J. McQ. Thomas, Enid L. Weatherhead, H. A. Williams, Margaret C. Winter and Susan S. Yang.

St. Bartholomew's Hospital Medical College

A post-graduate course open to all will be held at this hospital on June 17th, 18th and 19th. Further information may be had from the dean of the medical college.

Royal London Ophthalmic Hospital

The Gifford Edmonds prize at Moorfields has been awarded to Mr J. Bruce Hamilton of Hobart, Tasmania for an essay on the significance of heredity in ophthalmology. The prize is awarded biennially.

Central Midwives Board

This board has unanimously re-elected Sir Conyns Berkeley as its chairman. Mr John Bright Banister and Mr Eardley Holland have been appointed to fill vacancies in the membership of the board.

Toronto Anatomical Session

The fifty-third annual session of the American Association of Anatomists was held on March 25th to 27th at the University of Toronto. Prof. Fredene T. Lewis (Harvard) the president delivered an address at the dinner on the fundamentals of cell shape. There were 151 papers and thus many of them had to be presented simultaneously. Six round table conferences were held covering subjects like spore production, capillaries, modern conceptions of the neuron, gross anatomical research, heart and teeth. Anatomy now claims as its own all changes in cells having to do with function and there were papers dealing with subjects such as the hypophysis, the adrenal and other ductless glands, the adrenal-pituitary relationship in lactation, changes in the adrenals, livers, and thyroids of guinea pigs as affected by environmental temperatures and thymus, and the effect of cortical adrenal extract on sympathetic ganglia of adrenalectomized cats. There was much emphasis on the influence of heredity on form. Some of the papers bordered on the pathological field such as that on abnormal blood production in hydrops fetalis. One of many communications on the blood field that lymphocytes could develop in tissue cultures into myelocytes. Other papers were of the other anatomical type including a notable one on the arrangement of the cranial venous sinuses in the occipital region in man. Various aspects of the nervous system were also discussed. Seven motion pictures were shown illustrating such phenomena as fetal behaviour, leg transplantation and fetal respiration. An afternoon was set aside for the presentation of sixty demonstrations.

Dr Charles David Green, who died in St Thomas's Hospital on Monday, April 12th, aged 75, had retired from practice. Formerly M.O.H. for Edmonton, he practised with success in the City of London. He was exceptionally highly qualified and made useful contributions to our columns and to the *Transactions* of the Pathological Society.

New Maternity Home for Beckenham

At a meeting of the Beckenham borough council recently it was decided to build a new maternity home containing 38 beds at a cost of £40,640.

Falkirk Royal Infirmary

A new nurses' home is needed here and an appeal for £40,000 is to be made. For the first time in the hospital's history an adverse balance is reported, the deficiency on Dec 31st was £757.

Journées Médicales de Bruxelles

This congress will be held in Brussels under the presidency of Prof Albert Dustin from June 19th to 23rd. The speakers will include Sir Joseph Barcroft, F.R.S., Prof D Danielopolu (Bucharest), and Prof F Rathery (Paris). Dr R Beckers, the secretary general, may be addressed at 141, rue Belliard, Brussels.

Greater London Provident Scheme for District Nursing

An inaugural meeting to explain the purpose of this scheme will be held on Monday, April 19th, at 4 p.m., at the Grocers' Hall, Prince's street, E.C. The scheme seeks to provide an organisation self-sufficient and auxiliary to the existing district nursing services in the metropolitan area. Lord Horder and Miss Mercy Wilmshurst, general superintendent of the Queen's Institute of District Nursing, will be among the speakers. The executive committee may be addressed at 1, Sloane-street, S.W.1.

British Empire Cancer Campaign

In the absence of Viscount Hailsham, Sir Cuthbert Wallace, president of the Royal College of Surgeons, presided at the quarterly meeting of the grand council of the British Empire Cancer Campaign held on April 12th. The council was informed that the campaign would move into its new offices at 11, Grosvenor-crecent, next door to the present offices, on May 1st. The following grants, totalling £2900, were made, in addition to the bulk grants of last November and January: £1000 to be placed at the disposal of Mr F Dickens, D.Sc., director of research of the North of England branch of the campaign, at Newcastle, for the continuation of the special "short" wave investigations being carried out under his direction on behalf of the scientific advisory committee at head quarters; £1200 for the purchase of a plaque of radium in use by Dr F G Spear at the Strangeways Research Laboratory, Cambridge, an additional grant of £300 for 1937 to the Westminster Hospital, an additional sum of £300 to Mr F C Pybus for the salaries of his assistants and expenses during the second half of 1937, and a grant of £100 to Mr L H Gray, D.Sc., at Mount Vernon Hospital, in connexion with the neutron investigations.

Sir James Walton was unanimously elected a member of the Council.

Appointments

BARLOW, DONALD M.S. Lond. F.R.C.S. Eng., Hon. Assistant Surgeon to St John's Hospital, Lewisham.
BINNING, REX, B.A. Camb., M.R.C.S. Eng., Anaesthetist to the Royal Alexandra Hospital for Sick Children, Brighton, and to the Brighton and Hove Dental Hospital.
DUNCAN, A.S. M.B. Edin., House Surgeon, Hospital for Sick Children, Great Ormond street.
FRASER, ROBERT M.B. Aberd., D.P.H., Resident Medical Assistant at the City Hospital for Infectious Diseases, Newcastle upon Tyne.
LUMSDEN, A.G. M.B. Aberd., Hon. Assistant Ophthalmic Surgeon to St John's Hospital, Lewisham.
MACLEOD, HENRIETTA M.A. M.B. Lond., Assistant Medical Officer for Maternity and Child Welfare Work for Nottingham.
MCNEILL, JANE L. M.D. Belf., L.M., Medical Officer in the Maternity and Child Welfare Department at Birmingham.
ROBERTS, A.J. L.R.C.P. Lond., House Surgeon to the Evelina Hospital for Sick Children, London.

WALKER, J.V. M.B. Birm., M.R.C.P. Lond., D.P.H., Assistant Medical Officer of Health and Assistant School Medical Officer for Boodle.

WILSON, REGINALD M.D. McGill, D.O.H., House Physician, Hospital for Sick Children, Great Ormond street.

London Hospital.—The following appointments are announced:
GOWAR, F.J. SAMBROOK M.B. Lond., F.R.C.S. Eng., First Assistant to the Department of Thoracic Surgery.

GAVET, C.J. M.D. M.R.C.P. Lond., Paterson Research Scholar and Chief Assistant to the Cardiac Department and

LISTER, ARTHUR, M.B., B.Chir. Camb. F.R.C.S. Eng., First Assistant to the Ophthalmic Department.

Certifying Surgeons under the Factory and Workshop Acts: Dr F.G.A. BECKETT (Ely District Cambs), Dr J.O.S. WELLS (St Mary's Isles of Scilly, District, Cornwall), and Dr C.R. FIELDING (Tarrin District, Cheshire).

Vacancies

For further information refer to the advertisement columns.
Alderley Edge, Ancoats Hosp. Convalescent Home, Great Warford.—Hon. Visiting M.O. £50.
Baghdad, Royal College of Medicine.—Prof. of Pathology and Prof. of Bacteriology, each £150 a month.
Barking Borough.—Asst. M.O. £500.
Barnsley, Beckett Hosp.—Res. Surg. O. £300.
Bath, Royal United Hosp.—H.S. to Ear, Nose, and Throat Dept., at rate of £150.
Beckenham, Bethlem Royal Hosp., Monk's Orchard.—Cons. Surg. Also Radiologist 150 guineas.
Blackburn, Calderstones Certified Institution for Mental Defectives.—Whalley.—Deputy Med. Supt. £750.
Blackburn Royal Infirmary.—Res. H.S. £175.
Bradford, Royal Eye and Ear Hospital.—H.S. £180.
Bristol Mental Hosp.—Fourth Asst. M.O. £500.
British Postgraduate Medical School, Ducane road, W.—Three Part-time Demonstrators in Clinical Medicine each £100.
Canterbury, Kent and Canterbury Hosp.—Hon. Anaesthetist to Ear, Nose, and Throat Dept.
Cheltenham General and Eye Hosps.—H.S. to Eye, Ear, Nose and Throat Dept. £150.
Chester Royal Infirmary.—H.S. £150.
Chesleyfield and North Derbyshire Royal Hosp.—H.S. to Ophthalmic and Ear, Nose, and Throat Depts., at rate of £150.
Connaught Hosp., Wallhampton, E.—Cas. O. at rate of £100.
Croydon and Warwickshire Hosp.—Res. Cas. O. £125.
Coventry, Mayday Hosp.—Asst. Pathologist and Bacteriologist £350. Also two Jun. Res. Asst. M.O.s each £300.
Doncaster Royal Infirmary, and Dispensary.—Cas. H.S. £175.
Eastbourne, Princess Alice Hospital.—Res. H.S. £150.
Edgware, Redhill County Hosp.—Asst. Pathologist, £350.
Edinburgh Royal College of Physicians.—Kirk Duncannon Fellowship for Medical Research, £300.
Edmonton, North Middlesex County Hosp.—Jun. Res. Asst. M.O., at rate of £250.
Elizabeth Garrett Anderson Hosp. Euston road, N.W.—H.S. Asst. Surgeon to Throat, Nose, and Ear Dept. H.S. Physician to Children's Dept. Radiologist £200. Asst. Pathologist for Dept. of Morbid Anatomy, &c. £350.
Exeter City and County.—Temp. Asst. School M.O. and Asst. M.O.H., at rate of £600.
Exeter, Royal Devon and Exeter Hosp.—H.P. and H.S. to Ear, Nose and Throat Dept., each at rate of £150.
Fermanagh County Hosp. Enniskillen.—Surgeon Superintendent, £750.
Grimsby and District Hosp.—Jun. H.S. £150.
Haitax General Hosp.—Jun. Res. M.O. £250.
Hastings, Royal East Sussex Hosp.—Sen. H.S., at rate of £250.
Hertford County Hospital.—Sen. H.S., at rate of £200.
Hosp. for Sick Children, Great Ormond street W.C.—Out-patient Med. Reg. £175.
Hove General Hosp.—Jun. Res. M.O. £120.
Huddersfield Royal Infirmary.—Two H.S.s each at rate of £150.
Hull Royal Infirmary.—H.P. to Sutton Branch, and Second H.P. at rate of £100 and £150 respectively.
Ilford King George Hosp.—H.S., at rate of £100.
Kettering and District General Hosp.—Res. M.O. and Second Res. M.O. at rate of £175 and £125 respectively.
King's College Hosp. S.E. Squint Clinic.—M.O. £80.
L.C.C.—Asst. M.O.s, Grade I £350. Also Asst. M.O.s, Grade II, £250.
Lincoln County Hosp.—Jun. H.S., at rate of £150.
Liverpool and District Hosp. for Diseases of the Heart.—H.P., £110.
London Child Guidance Clinic 1, Canonbury-place, N.—Three Fellowships in Psychiatry each £300.
London Hosp. E.—First Asst. to Gynaecological and Obstet. Dept. £250.
London Jewish Hosp. Stepney Green E.—Hon. Clin. Asst.
London Lock Hosp., 283, Harrow road, W.—Res. M.O. to Men's Depts., at rate of £175.
Macclesfield General Infirmary &c.—Sen. H.S., at rate of £175.
Manchester, Booth Hall Hosp. for Children.—Deputy Med. Supt. £550.
Manchester City.—M.O. for Maternity and Child Welfare £50.
Manchester, Royal Children's Hosp. Pendlebury.—Res. Surg. O. at rate of £150.
Manchester Royal Infirmary.—Jun. Asst. M.O. £350.
Middlesbrough North Riding Infirmary.—Cas. O. £150.
Ministry of Health, Whitehall S.W.—Temp. Serologist, at rate of £850.
Nelson Hosp. Merion S.W.—Res. H.S. at rate of £100.
Newcastle General Hosp.—Res. H.S. £175.

Newcastle-on-Tyne, Wootley Sanatorium near Hazkam—Asst. M.O. £350
 Norwich, Norfolk and Norwich Hoop—H.S. to Spec. Depts., £150
 Nottingham General Dispensary Hyson Green Branch—Res. Surgeon £300
 Nottingham General Hoop—Res. Cas. O and H.S. each at rate of £150
 Oldham, Boundary Park Municipal Hoop—Res. A.M.O. at rate of £200
 Oxford, W'ingfield Morris Orthopaedic Hoop Hemlington—Res. H.S. £100
 Plymouth Prince of Wales's Hoop Devonport—Jun. H.S. at rate of £120
 Prince of Wales's General Hoop A—Hon. Clin. Asst. Princess Louise Kensington Hoop. for Children, St. Quintin Avenue, W—Hon. Radiologist.

MANCHESTER ROYAL INFIRMARY

TUESDAY, April 20th.—1.15 P.M. Mr. Geoffrey Jefferson: Surgery of Intracranial Aneurysms

FRIDAY—1.15 P.M. Dr. Crichton Brownwell: Demonstration of Medical Cases.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION

WESTERN INFIRMARY, April 21st.—4.15 P.M. (Western Infirmary) Dr. G. Macgregor-Robertson: Venereal Disease in Men.

NOTES, COMMENTS, AND ABSTRACTS

BLOOD PRESSURE AMONGST ABORIGINAL
ETHNIC GROUPS OF SZECHWAN
PROVINCE, WEST CHINA

By W R MORSE, M D McGill, LL D, F A C S

DIRECTOR OF THE COLLEGE OF MEDICINE AND DENTISTRY AND
HEAD OF THE DEPARTMENT OF ANATOMY, UNION
UNIVERSITY CHENG TU WEST CHINA AND

Y T BEH, M D

INSTRUCTOR IN ANATOMY AT THE UNIVERSITY

The blood pressure plays an important part in anthropology in relation to heredity, environment, social life, diet, attitude, stress and strain of ethnic groups. Publications dealing with the blood pressure of little known and isolated ethnic groups are probably not very extensive. Here is a report on three such groups, the Chwan Miao, the Ta Hwa Miao, and Noso (Lolo).

Ten expeditions* have been made by the senior author amongst the aboriginal ethnic groups of the borderlands of the above province to secure anthropological data. The blood pressure of the Chwan Miao was taken by Y T Beh and that of the Ta Hwa Miao and the Noso by Dr L G Kilborn, professor of

Miao chiefly in Yunnan and Kweichow, the Noso in Szechwan, Yunnan, and Kweichow.

Method—A Nicholson's mercury, or a Tyco's sphygmomanometer was used. The subjects were seated facing the experimenter, and a 12 cm cuff was applied to the right arm of the subject. The pressure in the cuff was raised until all sounds had disappeared, and then as the pressure in the system was lowered the first point at which sounds reappeared was recorded as the systolic blood pressure. As the pressure was still further lowered the point at which the clear sounds suddenly changed to dull and muffled ones (so called fourth point) was recorded as the diastolic pressure. Readings were made at various times of the day as they had to be taken whenever the subjects were available.

The recording of the blood pressure was but one item in a series of complete anthropological measurements carried out by members of our expedition into the Miao country.

The results on the Chwan Miao are set out in Table I.

Table II shows the results on the Ta Hwa Miao and the results on the Noso (Lolo) are given in Table III.

TABLE I
Blood Pressure of the Chwan Miao

Age group	Number examined	Systolic pressure			Diastolic pressure			Pulse pressure		
		Mean	Max	Min	Mean	Max	Min	Mean	Max	Min
16-20	3	103.5	110	94	69.7	81	58	32.3	30	30

physiology. Physical anthropological measurements and observations were made on the above groups. Photographs were taken but in only one group (the Chwan Miao) do the photographs indicate the individuals on whom the blood pressure and the other anthropological measurements and observations were taken.

All of these aboriginal groups are relegated by the pressure of the Chinese to the fastnesses of the mountains of the provinces. The Chwan Miao are found in Szechwan and Kweichow, the Ta Hwa

TABLE II
Blood Pressure of the Ta Hwa Miao

Age group	Number examined	Systolic pressure			Diastolic pressure			Pulse pressure

Total	150									
Aver		104			70			34		

TABLE III
Blood Pressure of the Noso

Age group	Number examined	Systolic pressure	Diastolic pressure	Pulse pressure
16-20	6	98.6	106	90
21-25	33	104.7	128	90
26-30	26	107.7	124	86
31-35	0	102.7	130	80
36-40	14	101.8	118	90
41-45	6	106.3	123	97
46-50	4	106.2	127	90
51-60	6	99.6	122	78
61	1	118.0		72.0
Total	103			
Aver		104.5		72.8

The blood pressure of these three groups is uniformly low, the Chwan Miao being somewhat the highest. There is no tendency towards an increase in the blood pressure with age.

All these people live in the mountains above sea level, the Chwan Miao at or about 3000 ft, the Ta Hwa Miao at 7-9000 ft, and the Noso at 5-10,000 ft. They all live in a fairly rigorous climatic environment not subject to extremes of temperature. The location of these groups is approximately Lat 28°-31° N and Long 100°-104° E, this section being in parts of Szechwan, Yunnan, and Kweichow provinces. None of these groups live in villages or cities but they are scattered about the countryside. They are agricultural and pastoral people, some are hunters.

In all cases the chief diet of these mountaineers is corn and not too abundant in amount, the Chwan

* These ten expeditions embraced the following groups—viz Tibetan Chlang, Gila Rong, Noso (Lolo) Black and White Bonce, Hsi Kan, Bo Lo Tsi, Ta Hwa Miao, Chwan Miao and Chang Chiao. Of these groups some 1206 individuals have been measured and observed but the statistical results have not been fully worked out.

Miao eat some rice. Meat is not used as a general diet, being almost entirely limited to wedding funerals and celebrations. Milk butter and cheese are not used in either group. Vegetables are sparingly eaten. They live on a restricted low diet. The sexual life of the Miao groups is rather free amongst themselves except the Christians. The Noso are not sexually free.

These groups are relatively isolated from the Chinese especially the Independent Noso of Szechwan. The Miao groups are not so isolated. They are living where might is right. All have been and the Noso now are very antagonistic with the Chinese. The Miao formerly very warlike are now subdued. The Ta Hwa Miao are practically *serfs* of the Noso.

SUMMARY

This paper reports the blood pressure of three ethnic groups as follows —

TABLE IV

Group.	Number	Age.	Systolic pressure.	Diastolic pressure.	Pulse pressure
			Mean	Mean	Mean.
Chwan Miao	143	10-70	109.7	72.1	38.0
Ta Hwa Miao	150	16-70	104.0	66.0	34.0
Noso (Lolo)	105	16-64	104.5	72.8	31.7

The blood pressure of the Noso and Ta Hwa Miao does not increase with age and the Chwan Miao only slightly so.

AIR RAID PRECAUTIONS AT PUBLIC SCHOOLS

MEMBERS of the Medical Officers of Schools Association met together on April 9th, under the presidency of Dr J. LAMBERT to hear an address from Dr STUART BLACKMORE, of the air raid precautions department of the Home Office. Dr Blackmore put before them the problem set by air attack and asked for suggestions as to how it should be solved by those in charge of schools. Of the three kinds of missile to be expected the first the high-explosive bomb was so powerful that the effects of a direct hit might be left out of account in devising preventive measures. The damage done by splintering and by the pulse-wave following the explosion could however be minimised. The gravest danger was from the incendiary bomb which produced a temperature of 2000 C. and was inextinguishable. From the fire-fighting point of view it would be useless to direct energy to using water or chemicals on the point of contact or the bomb, and they must be employed on the surroundings to limit the extent of the fire. Dr Blackmore placed the gas bomb last because it was the least dangerous of the three forms of air attack. If only the mass of the people could be given the necessary minimum of instruction and training. Gas if used against an unprotected and ignorant populace was absolutely devastating both in producing casualties and in ruining morale; but against an instructed mass of people its effects were less to be feared than those of the high explosive and the incendiary bomb.

It was agreed that each public school should make suggestions suitable to its own circumstances and situation.

PROTECTION OF MOTHERS AND CHILDREN IN RUSSIA

BEFORE the war infant mortality in Russia was about 270 per 1000 live births, and in 1911 a third of all deaths in Moscow were estimated to be among children under five. Immediately after the Revolution a department for the protection of motherhood and infancy was set up and the comprehensive service it has instituted is described and illustrated in a book entitled *Nursery School and Parent Education in Soviet Russia*.¹ According to the authors, the State takes entire responsibility for protecting its women and children and though at present the standard varies greatly between towns and country districts, the ultimate aim is to provide adequate intelligent care in nursery institutions for every young child in the Union. A woman engaged in physical work is now entitled to eight weeks leave before and eight weeks after confinement with full wages, and the nursing mother may take half an hour after every three and a half hours of work to feed and attend to her baby. Consultation centres cater both for mothers and children and the doctor in charge of a centre is held responsible for certain streets where he must visit any infants who are seriously ill besides those suffering from infectious illness. Creches are of different types according to the mother's occupation. A factory worker takes her baby to the creche attached to her place of work to remain there as long as she is on duty. Many women are employed on collective farms and summer travelling creches follow them round from place to place the babies being kept for as many as eighteen hours a day when necessary. Travelling in Russia is notoriously slow but it is enlivened for mothers and infants by the establishment of special rooms with nursery equipment at the larger railway stations. A mother with a child is expected and encouraged to break into the queue when waiting to take tickets and on some trains special coaches for mothers and children are provided.

Nursery schools only cater for children up to the age of four but they have a strong political bias. An account of one school shows babies of fourteen months playing in a room with a portrait of Lenin for their inspiration; from infancy the air of education is collectivism teachers being instructed to think out every part of the apparatus and play material in the light of the educational goals of the State. Furniture and equipment are carefully designed and the toys are exceptionally good many being made by peasants from the simplest materials. Probably at times both teachers and children forget that their institution is a principal weapon in the struggle for socialism in the nursery field and play like anybody else just for the fun of the thing.

Education of parents is carried on by parent teacher meetings, by exhibitions temporary and permanent by literature and posters. Research departments are working in Moscow and Leningrad studying both normal and abnormal children under three years of age and special attention is devoted to the training of deaf and dumb children.

E MERCK'S JUBILEE REPORT

It was in January 1897, that the chemical works of E. Merck in Darmstadt began to issue a summary of short and useful information about new pharmaceutical preparations for the use of doctors and pharmacists. It was not the firm's first venture of the kind because Heinrich Emanuel Merck (1791-1850) whose portrait is attached to the jubilee issue now before us had already embarked on a serial entitled *A Cabinet of Novelties* and had collaborated with Lillie, Trommsdorff and Meier.

¹ By Vera Fedayev Ly. Formerly Senior Scientific Worker of the Central Institute for the Protection of Motherhood and Infancy in collaboration with Betty Smith Hill, Ph.D. Emeritus of Education, Columbia University, New York. London: H. K. Lewis, Paul, Treves, Trubner and Co. Ltd. 1936. Pp. 263. 10s. 6d.

in the *Annals of Pharmacv*. For half a century the *Jahresbericht* has appeared, giving what its editor regards as the "really important" in the pharmaceutical year. The report has contained original articles from the firm's own laboratories and often contributions from outside authors, of which one of the earliest was J. v. Merz's "Physiological and Therapeutic Investigations on the Action of some Morphine Derivatives." The present volume is prefaced by congratulatory notes from directors of pharmacological institutes all over the world including Heubner (Berlin), Tschirch (Bern), Krehl (Heidelberg), Hansen (Oslo), Aschoff (Freiburg), Marinresco (Bucharest), Eppinger (Vienna), Barger (Edinburgh), Cesa-Bianchi (Milan), Tsi-Lung (Shanghai), Crocco (Buenos Aires), Lebeau and Tiffeneau (Paris). The next 170 pages contain original contributions dealing for the most part with hormones, vitamins, and the newer alkaloids, leaving 120 pages for brief summaries of some 600 preparations and drugs, with precise references to the literature. Merck has not been unmindful of foreign readers, for French, Russian, Spanish, and English editions of their annual report have appeared for many years. A general index of all 50 numbers is promised in the near future.

PALLIATIVE TREATMENT OF CANCER

A PLEA for a different mental attitude towards methods of treating cancer is made by Dr. B. R. Shore.¹ His thesis is that to prolong life with the greatest possible measure of physical and mental comfort is the goal in treating all chronic non-infectious diseases, including cancer. Shore holds that the modern practice of classifying treated cases of malignant disease as three-, five-, or ten-year "cures" is unfair to existing therapeutic methods which should also be credited with the vast measure of physical and mental relief afforded to patients who do not survive long enough to fall within any category of "cure." The biology of any given cancer and of the patient suffering from it are two unknown quantities, no patient is too ill for therapy in some form and the prognosis is often quite uncertain. To illustrate his point the author quotes six cases of apparently inoperable carcinoma of breast on whom palliative mastectomy followed by radiation was done. Three of the six are still alive without recurrence 8 years later, one died of recurrence after 7 years and another after 6 years, and one died of heart disease 7 years after operation. The importance of histological diagnosis in cases of cancer is emphasised. It is a counsel of perfection that biopsy specimens should be of adequate size and taken from representative portions of the growth by gentle surgical means. Gynecologists might ask whether curettings from a case of suspected carcinoma of the body of the uterus may be regarded as adequate biological material, it would be difficult to obtain larger portions of material in such cases without resorting to laparotomy. A disturbing fact disclosed by an investigation of 744 consecutive cancer cases admitted to St. Luke's Hospital, New York, to which Dr. Shore is attached was that only 21.4 per cent were radically operable. In a group of 255 private patients, 53 per cent were radically operable, a proportion considerably higher though still falling far short of perfection. Making due allowance for other factors, the conclusion is reached that cancer is detected earlier among the better-to-do patients. This is what one would expect

Prof. A. E. NAISH writes: "My attention has been called to recent articles in the provincial press in which it is stated that a research group is working at Sheffield University under my direction investigating the treatment of haemophilia. I wish to state most emphatically that these articles have been published without my knowledge, and that, although I have been associated with the work, it is not being done under my direction."

Births, Marriages, and Deaths

BIRTHS

- BEVAN.—On April 9th at Devonshire place W., the wife of Dr. Charles E. Bevan, Colonial Medical Service Cyprus of a son.
- GRANT NICOL.—On April 8th at Wimbledon, the wife of Dr. O. Grant Nicol of a daughter.
- LIST.—On March 31st the wife of Dr. H. M. List, of Rochdale of a son.
- McKIBBIN.—On April 9th at Blackheath the wife of Major F. McKibbin, R.A.M.C., of a son.
- NEWTON PRICE.—On April 11th, at Hove, the wife of Dr. E. Newton Price of a son.
- O'CONNOR.—On April 8th the wife of Dr. W. J. O'Connor High Wycombe of a daughter.
- PATERSON.—On April 4th at Portsmouth the wife of Dr. Gerald Paterson, of a daughter.
- PORTER.—On April 7th, at Faversham the wife of Dr. T. W. Herdman Porter of a son.
- THURSTON.—On April 8th, the wife of Dr. Gavin Thurston, of Clapham Common of a son.
- WATERS.—On April 6th the wife of Captain H. S. Waters, I.M.S. Presidency Surgeon Bombay, of a daughter.
- WHITE.—On April 13th at Belsize Park gardens, N.W., to Sylvia wife of Norman White F.R.C.S.—a son.
- WRIGLEY.—On April 8th at Hamilton terrace N.W., the wife of Arthur Joseph Wrigley M.D. Lond. F.R.C.S. Eng., of a son.

MARRIAGES

- GREGGIERSON—CAMPBELL.—On April 10th at Christ Church Westminster, Dr. Gerald J. Greggier of Adelaide S. Australia, to Sheila elder daughter of Mr. and Mrs. W. R. Campbell of Sydney N.S.W.
- WHITFIELD—DENCE.—On April 3rd at St. Mark's Church, Torquay, George J. Newbold Whitfield, of Sunderland, to Audrey Priscilla Dence M.B. Lond., daughter of the late Rev. A. T. Dence formerly of Abbotskerswell and Mrs. Dence Torquay.

DEATHS

- BURTON.—On April 6th, at Clifton-court N.W., Alfred Henry Burton M.D. of Laxfield House Suffolk aged 84.
- GUTHRIE.—On April 13th at Wimbledon Robert Lyall Guthrie O.B.E., M.D. C.M. Edin. Lt. Col. R.A.M.C. (T), Barrister-at-Law, Coroner Eastern District County of London.
- JACKSON.—On April 5th John Luke Jackson M.B. B.Ch. Edin., son of the late Rev. John Jackson D.D. Ballycastle.
- LEAK.—On April 10th at Winsford, Cheshire Hector Leak M.R.C.S. Eng. in his 81st year.
- MURPHY.—On April 6th at Liphook, Hants, William Murphy M.B. Edin. in his 83rd year.
- PECK.—On April 6th at Bridgnorth Salop, Awdry Peck M.A. Oxon. M.R.C.S. Eng. aged 89.
- SMART.—On April 7th at Liverpool David Smart M.B. Edin. V.D. Colonel A.M.S.T., for 36 years Medical Officer in charge Smithdown road Hospital, Liverpool.
- TIGHE.—On April 4th, at Castlerock Co. Roscommon Ireland J. W. Tighe L.R.C.P.I. & L.M. Surgeon Commander Royal Navy (ret'd.) only son of Dr. J. M. Tighe and the late Mrs. Tighe of Melbourne.
- TURNBULL.—On April 11th at Southsea following an operation Surgeon Captain Hugh Prideaux Turnbull, R.N. (ret'd.) of Emsworth.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages and Deaths.

A CONFERENCE ON PROSTITUTION.—The French Government has introduced a Bill to abolish *maisons tolérées* and to organise the fight against venereal diseases. The International Abolitionist Federation is taking the opportunity to organise an international congress in Paris from May 20th to 22nd. The problems of prostitution and venereal disease will be studied during this congress from three points of view—legal, medical, and moral. Dr. Veldhuyzen, director of the Wilhelmina Hospital at Amsterdam, who will open the discussion on the medical aspect, will describe the progress in treating venereal diseases and explain why voluntary methods of treatment have proved more successful than compulsory methods. Miss Alison Neilans, general secretary of the Association for Moral and Social Hygiene, will deal with the effect of regulation on morality, youth, and the women concerned. Information about the congress may be had from the Secretariat of the Federation, 8 rue de l'Hôtel-de-Ville, Geneva.

ADDRESSES AND ORIGINAL ARTICLES

THE PREVENTION OF PULMONARY TUBERCULOSIS AMONG ADULTS IN ENGLAND IN THE PAST AND IN THE FUTURE *

By P. M. D. AROY HART M.D. Camb. F.R.C.P. Lond.
ASSISTANT PHYSICIAN TO UNIVERSITY COLLEGE
HOSPITAL, LONDON

IN 1870 Dr Milroy the founder of this lectureship wrote as follows of a group of diseases that included tuberculosis: No question of public hygiene is perhaps of more importance in respect alike of individual suffering and of the welfare of communities than the *Ætiology* of the chronic Cachexia.

In spite of the discovery of the tubercle bacillus by Koch three years later it is clear that pulmonary tuberculosis is still one of the major problems of medicine. Thus at the present time it is responsible for the deaths of about 25 000 persons annually in England and Wales alone, a figure that amounts to about 5 per cent of deaths from all causes. Among young men and women of 15-24 it causes more deaths than any other single disease. Indeed its death rate at that age is about two-thirds of that of all other diseases taken together. It is also costly in money: for in 1933-34 the local authorities of England and Wales spent on their tuberculosis services nearly £4 000 000, or 7 per cent. of their total expenditure under the heading of public health (Ministry of Health 1935-36). This sum represents about 2s. per head of the population of the country.

Tuberculosis therefore, still presents a health problem of great medical and economic importance. I shall try to show that in the future as in the past success in its solution is most likely to be attained by measures of prevention. The term preventive will be used here in a broad sense to comprise all remedial measures other than the actual technique of treatment. Thus it will cover the prevention of progressive lesions after infection has taken place, the prevention of further advance in such lesions after their presence has been recognised, and the prevention of their breakdown after the stage of regression is attained.

The age of 15 will be taken as the dividing line between the child and the adult, because it is at this age that in England most members of the working class enter the labour market suffering a radical change in their mode of living.

Two types of pulmonary tuberculosis will be recognised as occurring in the adult though a hard and fast separation between the two may in time prove to be unjustified.

1 The first and less common type may accompany first infection—with its change from negative to positive tuberculin reactivity—when this process takes place in adult life instead of as is more common in urbanised communities in childhood. The lesions take the form of pulmonary infiltrations around the primary focus (which may occur in any part of the lung) enlarged tracheo-bronchial glands, pleurisy, erythema nodosum &c. Because these lesions are of the kind sometimes associated with first infection received in childhood the term *child hood type of tuberculosis* is often applied to them also in the adult.

2 The second type is much the more common in this country and is usually known as the *adult type*. Its progressive lesions are due to it is usually held to the extension of a reinfection process that occurs peculiarly in the apical or subapical region of the lungs of persons already first-infected.

Many aspects of these two types of pulmonary lesions remain obscure (for different views of pathogenesis see Ople 1935 Blacklock 1936 Pagel 1936). Nevertheless additions to knowledge during the past two decades permit us to indicate fresh lines of activity in the field of prevention of pulmonary tuberculosis among adults.

Social Preventive Measures Applicable to the Community

FACTORS RESPONSIBLE FOR THE TREND OF PULMONARY TUBERCULOSIS IN ENGLAND

Mortality figures, which provide the most complete available estimate of the past trend of pulmonary tuberculosis showed a satisfactory decline in all age-groups in England from the middle of the last century until the beginning of the present one. Latterly however although the figures for most age groups have continued their downward course except during the late war the mortality in young adults (aged 15-24) more especially in young women has shown a less rapid decline. Thus for young women the mortality in 1930-32 was only 4 per cent. lower than in 1911 as against a reduction of 30 per cent. for women aged 25-44. There is reason to think that the situation is now again improving but this is still uncertain.

A decline in mortality from any disease may result either from a decrease in its morbidity or from a fall in its case fatality. Comparison of mortality and morbidity figures for pulmonary tuberculosis since 1923 shows an approximate parallelism between the two (see Ministry of Health 1935a). If this can be assumed to be true also of earlier periods we arrive at the important conclusion that the decline in mortality is probably due to the decrease in incidence of new cases rather than to a reduction in the case fatality.

It is now widely accepted that the general decline in pulmonary tuberculosis has been mainly the result of improvement in the general social and economic conditions of the mass of the people. Although specific antituberculosis measures might be expected to have played an important part in the reduction it is hard to determine the extent of their contribution at least in the case of adults. For the general decline in mortality from pulmonary tuberculosis began in this country before any specific measures were taken against the disease, and has been accompanied by a substantial decline in mortality from all other diseases taken together. On the other hand, the recent check in the reduction of pulmonary tuberculosis mortality among young adults—a check that was not shared by the mortality from other diseases—has occurred during a period when interest in matters of public health in general has been greater than ever.

This serious check in the decline of tuberculosis mortality among one of the economically most important groups of the population has naturally attracted much attention and it seems of great consequence to establish the factors responsible. The following is a resumé of certain parts of work in preparation by Payling Wright and myself.

Stocks (1936) rightly points out that one must consider not only the retarded decline in the country as a whole, but also the differences in decline experienced from one locality to another. He attributes the general retardation in the age group 15-24 to the after-effects of war time privations. But though such privations readily account for the temporary rise in tuberculosis mortality both among child and adult civilians while the war was in progress, they cannot be accepted as a complete explanation, since in young females, at any rate, the check in decline in mortality began some years before 1914. To explain the local differences in mortality decline, internal migration of young adults in search of better economic conditions has been advanced as an important factor by Bradford Hill (1936), these migrants being, he believes, less likely than non migrants to develop pulmonary tuberculosis. This belief in the superior health of migrants in recent years may be disputed, and even if correct, migration will only partly account for the local differential fall in mortality, as indeed Bradford Hill himself is ready to admit.

It seems possible, in our view, to ascribe both the decline in the country as a whole and the local differences to the reaction upon health of associated social conditions, to which, it is suggested, young adults are especially sensitive.

IMPORTANCE OF VARIOUS SOCIAL FACTORS IN PULMONARY TUBERCULOSIS

(1) *Nutrition and housing*—If it is true that the trend of pulmonary tuberculosis has hitherto been mainly the result of social measures not especially directed to this disease, which social factors are of major importance? According to current belief these are housing, nutrition, and fatigue, and clothing, heating, and hygiene.

Housing conditions affect the frequency and intimacy of personal contact, and consequently the spacing and dosage of droplet infection. They may also perhaps influence individual resistance. It is doubtful if either nutrition or fatigue has any influence upon the actual occurrence of tuberculous infection, which is predominantly the result of contact. On the other hand, they probably affect the course of the tuberculous process once infection has taken place.

It is difficult to separate the importance of these various individual social factors because, being to a large extent determined by income, they are usually correlated with one another. On Tyneside Bradbury (1933) found a relationship between tuberculosis and both overcrowding and undernourishment (as judged by deficient dietary) and concluded that both these social factors are important as causes in tuberculosis. This agrees with the high degree of correlation found between overcrowding and adult pulmonary tuberculosis mortality in different localities—e.g. by Hart and Wright for English county boroughs. The separate importance of undernutrition agrees with the clinical observation that adequate diet is important in treatment of the disease, and also with the striking evidence of the effects of food shortage on tuberculosis mortality that was provided by the late war.

The rise in tuberculosis mortality then seen involved not only belligerent countries but also some neutral states affected by food shortage. In England and Wales the total civilian deaths from tuberculosis during the years 1914-18 were 18,000 more than would have occurred had the death rate continued at the same figure as in 1914. But the worst effects were seen in Germany and Austria where the qualitative and quantitative reductions in food allowance were the most extreme. It has been estimated that Germany lost an extra 230,000 civilian lives from tuberculosis as a result of the war and subsequent economic depression (1914-27) this works out as one person for every ten fatal military casualties.

While the main cause of the war rise is generally believed to have been the shortage of food, the employment of large numbers of persons in injurious trades, and overcrowding due to shortage of fuel, may also have played a subsidiary part (see Beveridge 1928, Memorandum 1936).

If, as seems probable, deficiencies in housing and in nutrition predispose to pulmonary tuberculosis, it is desirable to consider the present position of the country with regard to each of them.

(2) *Deficiencies in nutrition and possible remedies*—It is still unknown whether shortage of any particular food factor encourages tuberculosis. Out of the polemics that have surrounded the subject of nutrition, however, is emerging a rather new conception which may be of great importance in our future attitude towards the prevention of tuberculosis. According to this conception, a diet sufficient for optimal health should be aimed at in order to maintain physique and prevent disease (see Orr 1936, p. 12). While the composition of such an optimal diet cannot yet be stated with complete certainty, enough is known of the particular functions of individual food stuffs apart from their energy value to be sure that it exceeds, both in quantity and in quality, the diet previously regarded as adequate for minimal health—i.e. to prevent actual starvation or malnutrition in the older sense.

The main direct evidence for the existence of suboptimal nutrition has been provided by dietary or feeding experiments in school children and adolescents (e.g., Cory Mann 1926, Orr 1928, Orr and Clark 1930, Leighton and McKinlay 1930, Friend 1935). These investigations are supported by the beneficial results of administering a liberal diet to substandard army recruits for short periods (see Duff Cooper 1937). These latter results are of particular interest since the subjects are drawn from the age group whose tuberculosis incidence has been given rise to especial anxiety in recent years.

Inquiries into working-class dietaries in selected population groups provide information from another angle on the prevalence of suboptimal nutrition. In some instances individual dietaries have been assessed (Cathcart and Murray 1936, Newcastle-on-Tyne 1937), while in others group-averages of dietaries in relation to income have been used—a procedure that involves certain assumptions (e.g., Orr 1936). Most of the investigators have found their groups under examination to contain many persons who are consuming diets which cannot be fairly accepted as up to any reasonable optimum.

The desirability of raising the level of nutrition in the nation is now recognised. The chief measures put forward for securing such improvement are an increase in food purchasing power, education in the apportionment of available means, and, where necessary, direct supply of suitable nutrients as a part of the social services. The relative emphasis to be laid upon the first and the second of these measures has been disputed, but a recent statement of opinion may be quoted in this connexion—

"It is undoubtedly true that, even if there were abundant money for food expenditure in every household, ignorance and stupidity would often prevent the maximum nutritional benefits from being obtained, as they certainly do in many of the houses of the well to do at present. At the same time, it is equally certain that the limiting factor in a large section of the community is food purchasing power. In any steps taken to improve the physical fitness of the community, both aspects of this problem, the educational and the economic, must therefore be dealt with." (Medical Research Council 1936)

It is clear that no amount of education will overcome the restricted food purchasing power of a substantial section of the people, for the latter as

increase in real earnings or in the direct supply of suitable nutrients is therefore an essential.

Another fundamental condition of improvement is the availability of suitable foodstuffs for distribution and purchase. This is largely bound up with agriculture and international trade and is being studied by the League of Nations Committee on the Problem of Nutrition, which has (1936) issued an interim report. It is to be hoped that the recommendations of this committee will lead to better planning of the supply of suitable nutrients at prices within working-class means, and will obviate in some measure the unfortunate restriction in supplies that have resulted from recent schemes for raising the price levels of important internally produced foodstuffs in the interests of a limited section of the community.

(3) *Housing and its improvement*—Though we have no certain knowledge of what constitutes an entirely satisfactory standard of housing in relation to the prevention of tuberculosis we may be sure that for accommodation to be suitable it should comply at least with a standard of overcrowding such as that of the Housing Act, 1935 the survey for which showed a substantial proportion of the population to be living under sub standard conditions.

This Act marks an advance in that it encourages the eventual reduction by local authorities, of overcrowding in all areas to the same standard, whatever be the amount shown to be present by the recent survey. So far as the prevention of tuberculosis is concerned probably the best indications of progress in a local authority area after each year's working would be: (a) the number of persons formerly living under overcrowded conditions who have been rehoused during the year expressed as a percentage of the total number reported as overcrowded at the time of the recent survey and (b) the percentage of the population still living in overcrowded conditions at the end of the year. Such figures might give more valuable information from the health standpoint than would the mere number of persons rehoused which measures the absolute rate of improvement. It is of course essential that rehousing should not force the tenant to reduce expenditure on food, clothing and other necessities beyond the margin of safety because of increase in rental and fares otherwise more harm than good may result (McGonigle 1933 McGonigle and Kirby 1936).

FUTURE IMPROVEMENT IN STANDARD OF LIVING

We have implied that raising of the level of nutrition and housing would help to prevent pulmonary tuberculosis. Now housing, nutrition and various other factors when integrated determine the general level of social conditions or standard of living. We could, therefore have taken the standard of living as a whole and discussed the indications for its improvement. And from the influential part played in the past by a rising standard of living in reducing tuberculosis in this country (see above) together with the evidence that the mortality still differs considerably at different social and economic levels (Registrar General 1931 Greenwood 1935) we might justifiably have concluded that the average standard of living, of the working-class is still inadequate to provide full health and that a continued rise would be a preventive measure of the first importance. And if this be true of a rise in the average level it applies even more where living conditions are below the average.

The facts that in this country at least the standard of living has improved except where unemployment is prolonged and acute that knowledge of the nature of food has increased and that it has been possible to mitigate hardships by regulated insurance and assistance do not afford reasons for relaxing efforts but are an encouragement to persevere. The problems of want are now of manageable dimensions (Bowley 1936).

Social Preventive Measures Applicable to Tuberculous Families

We must now consider certain social measures embodied in the national tuberculosis scheme that are specifically directed to tuberculous persons and their families. These operate from the time of notification, and are concerned with the family of the patient during his absence for residential treatment, and later with himself in addition after his return home. Their chief objects are to maintain the standard of living of the family to prevent spread of the disease among its members and to prevent relapse. They probably confer most benefit on persons whose condition is diagnosed before it reaches the advanced stage and whose lesions cease to progress unfavourably or begin to regress as a result of their residential treatment. Unless bed rest for sufficient time to attain clinical cure comes to be found practicable as a rule for such patients the subsequent few years will remain a critical period for many of them and after care will continue to play perhaps as important a part as the original form of treatment in determining the ultimate prognosis. The care and after-care of these patients and their families rather than of advanced cases with little hope of recovery will be discussed here.

INFLUENCE OF ECONOMIC STATUS UPON PROGNOSIS AND OF PROLONGED ILLNESS UPON ECONOMIC STATUS

For a proper understanding of the functions of social care and after care the influence of economic status of the patient upon the ultimate results of treatment must be recognised. This influence as judged by case fatality has been pointed out by many authorities (see MacNalty 1932a, Burnett 1932) and is supported by Bentley's (1938a) report on the recent experience of the London County Council with pneumothorax treatment. There are grounds for the view that the major function of the care and after-care organisations is to provide for the poor some of the more essential health facilities which the rich are able to buy for the effects of the presence of a tuberculous member in wealthy families and in the families of many sections of the working class are often very different.

The patient of ample means returning home from sanatorium, can often afford to absent himself from his duties until advised by his doctor that it is quite safe to resume them. When he does so he is often able to arrange that at first they shall be less arduous, or that he can have intervals for rest and recuperation. At home he can make special hygienic provisions and can arrange suitable sleeping accommodation while the standard of living of his wife and family will not become seriously affected by his disability provided this be not unreasonably prolonged.

The working-class patient after the benefit of a not dissimilar treatment in sanatorium (which in the case of the London County Council area, has been free during the past three years) returns to a home environment where the provision of suitable hygienic arrangements may be difficult and of separate sleeping accommodation (see Bentley 1938a) impossible even under conditions that would not constitute actual overcrowding under the 1935 Housing Act. Unless he is fortunate enough to have substantial savings or private sickness insurance the standard of living of his family will usually have become lower than it was before his illness and its resources will now be further strained by the return of a non-contributory member. Unless some portion of the patient's wage continues, his income will eventually consist of sickness insurance benefits, originally designed to tide over short periods of illness and—in the case of National Health Insurance—these will be halved after six months.

This income will be unable to meet the week's expenses for a man, wife, and several children of school age unless sufficient contributions are available from any additional earners in the family, and it may therefore have to be supplemented by private charity, or by public assistance. The dietary of the family, even if supplemented by grants of extra milk to the children, and of extra nourishment to their father, will usually be restricted compared with what they were when the father was at work, and while it may seldom become less than that regarded as adequate to prevent gross malnutrition, it must often fall below any reasonable standard for optimal health. Diversion of food to the patient on sentimental grounds intensifies risk to the remainder of the family. Under such circumstances the wage-earner, anxious to restore his family's standard of life to its former level, fearing or knowing that his job will not continue to be kept open, or—should he already have lost it—unwilling to risk refusing the offer of another one, not infrequently returns to work too soon. This is especially harmful because he has small chance of obtaining light work, or of transferring from an unsuitable occupation.

This gloomy picture shows how pulmonary tuberculosis in the primary wage earner of a working-class family accentuates just those social differences between himself and the head of a wealthy household that probably made him more liable to develop the disease in the first instance. As Sir Arthur MacNalty (1932d) puts it—

"Tuberculosis occurs most frequently in persons who are badly housed, who live under conditions of over crowding and whose earnings are frequently inadequate to secure more than the bare necessities of life. The occurrence of tuberculosis in its turn increases the poverty of the family still more and the unfavourable conditions become intensified, thus reducing the chances of recovery for the patient and increasing the probability of the spread of infection to other members of the household."

It is therefore not surprising that the similar sanatorium treatment obtained by poor and rich, with its equally satisfactory immediate results, is followed by a divergence in the subsequent course of the disease as it affects the patient and his family. To find the best means of mitigating these inequalities is thus an after care problem of the first importance.

MEASURES OF SOCIAL AFTER CARE

Possible guiding principles—The following points of principle might reasonably serve as the objective

(1) That the dietary of the patient, and also of each member of his family in contact with him, should be substantially higher than the minimum standard at present regarded as sufficient to prevent clinical malnutrition in the older sense and should correspond rather to standards for optimal health, and that separate sleeping accommodation (as defined by Bentley 1936a) and not merely "non-overcrowded" premises should be available for the patient.

(2) That the family income should to some extent be related to its level before the illness of the patient, if he was in employment, so that he be not tempted to return to full or unsuitable work before fit to do so.

(3) That, on the view that the prospects of cure in slight or otherwise favourable cases of pulmonary tuberculosis are prejudiced by the social deterioration apt to follow prolonged absence from remunerative work, social expenditure on care and after care in such cases should be treated, for a limited period after diagnosis, as on an equal basis with the medical expenditure on their residential treatment.

How far are these principles being translated into practice?

Basic measures—Within the limits of the powers assigned to them, medical officers, health visitors, nurses, social workers, and others in the care and after care organisations make every effort to supply the basic needs of tuberculous families. Among

their contributions are preferential treatment in rehousing, home supervision and nursing, extra nourishment to the patient, and public assistance. Yet only too often the good work of residential treatment is speedily undone. The question therefore arises whether wider powers should be sought. If policy were to be developed according to the principles just outlined, an increase in national expenditure would probably be required. It could, however, be argued that this would be justified financially by a decrease in the number of failures following residential treatment that had already cost the community a considerable sum.

In order to provide for such increased expenditure, it might be necessary to create a special insurance fund for tuberculosis (and perhaps for certain other prolonged but hopeful illnesses) administered under National Health Insurance, or to permit local authorities to raise their scales of assistance or to make larger grants in kind for all members of affected families. Some progress in this direction has already been made: for example in Sheffield the rent due from a tuberculous family may be paid by the local authority after adequate rehousing has taken place.

Rehabilitation and re employment—Rehabilitation and the provision of lighter or more suitable work for tuberculous patients also form an essential though difficult part of after care activities. Two of the present experimental schemes must be mentioned.

The first is the *village settlement*, complete with industries. The best known example is Papworth, so ably conducted under Sir Pendrill Varrier-Jones. Here, and at Prestor Hall, a somewhat similar institution, patients—usually those with intermediate or somewhat advanced disease—settle with their families semi-permanently (Papworth 1936, London County Council 1935a). It has been suggested (Marx 1936) that at most 10 per cent of ex-sanatorium patients are suitable for this type of life.

The second consists of *workshops and cottages at sanatoria*, e.g. in Wales and at Birmingham—which allow patients to remain beyond the usual course of treatment. Not only temporary work, but also instruction in the hygiene that should be aimed at on return home is thus available (Powell 1926, Ministry of Health 1935c).

The wider development of settlement, workshops, and cottages at or in connexion with the various municipal sanatoria seems to offer a definite advance in after care. But even with such provisions on a large scale, there would remain a great mass of patients with slight or intermediate disease, and with good or fair ultimate prospects of health, who require rehabilitation in the city environment where their homes are situated. Many of these patients, after return home from sanatorium, are—for some time at least—unfit to resume full time work at their former occupations, but would be capable of safely undertaking short-time work or of transferring to fresh occupations involving less arduous duties.

It is hard to see any satisfactory solution of this part of the problem without the active co-operation of industry. In the Soviet Union attempts are being made to solve it as follows—

In some types of case ordinary factory work is curtailed, but the hours are, say, only half time; the balance of pay being made up from social insurance funds. Alternatively, a room may be provided with a conveyor belt that moves at reduced speed—a scheme that seems less practicable. For other types of case special workshops are provided from social funds. Stress is laid upon the desirability of maintaining the skilled man in skilled work even though his occupation within his original industry grade may be changed.

The medical authorities of the factories are responsible for making these arrangements for their substantial tuberculous workers, and for regulating their hygiene.

conditions both in the factory and at home. For those whose home conditions are unsatisfactory night sanatoria are available in their own districts; the latter provide meals and sleeping accommodation under better conditions of hygiene and with a smaller risk of conveying serious infection to contacts (see Webb and Webb 1936 *Lancet* 1936 Dobbs and Russell 1937).

In this country an arrangement whereby doctors could secure light work in industry for their tuberculous patients with greater regularity than at present would be of value, though the existence of able-bodied unemployment would make its function difficult while the provision of night sanatoria in cities for the use of workers whose home conditions are unsatisfactory would also be useful.

Conclusions on Social Measures of Prevention

Social measures are important throughout the course of pulmonary tuberculosis for not only do they influence the liability to develop progressive lesions but they also affect the ultimate results of treatment. Improvement in the standard of living of the mass of the people and extension and intensification of the activities of the care and after-care organisations would be valuable measures of prevention.

(To be continued)

SCURVY AND GARDITIS

By STEPHEN TAYLOR, B.Sc. M.B. Lond.

GROCIUS COMPANY RESEARCH SCHOLAR ATTACHED TO THE MEDICAL UNIT ST THOMAS'S HOSPITAL

That scurvy may be associated with cardiac lesions was shown by Erdheim (1918). He dissected many children who had died of scurvy in Vienna in the post-war period. Two thirds of the hearts showed hypertrophy of the right ventricle. In the other one third the scurvy was only incipient or mild. In the more severe cases both ventricles were hypertrophied. The older the children the more constant was the enlargement. Sometimes cardiac failure led to hepatic stasis but this was also seen in the absence of heart changes. Findlay (1923) produced chronic scurvy in guinea pigs (hereinafter called pigs) and infected them with pneumococci and staphylococci; post mortem he found fatty degeneration of the heart muscle. Höjer (1924) examined the cardiac muscle of 10 scorbutic pigs. He found the same changes as in the skeletal muscle (hyperemia and atrophy). Occasionally there was necrosis going on to calcification. Changes appeared during the latent stages of scurvy. Meyer and McCormick (1928) and Bessey, Menten and King (1934) found fatty degeneration and hemorrhage into the heart muscle in uninfected scurvy. Rinehart and Mettler (1934) while studying the response of scorbutic pigs to intradermal infection with β hemolytic streptococci found degenerative and proliferative changes in the heart valves and muscle.

In control pigs the valves were compact with abundant wavy fibres; the nuclei were arranged axially with no visible cytoplasm. The myocardium showed occasional accumulations of lymphocytes, with or without mononuclear cells and fibroblasts. In scorbutic pigs the valves usually showed hyaline or mucoid degeneration of the fibres, with fragmentation and lack of axial arrangement. Occasionally there was slight proliferation of the endothelial and subendothelial cells. In the scorbutic infected pigs the valves, especially the mitral valve were greatly swollen. They showed eosinophilic hyaline areas and paler mucoid material. Two-thirds of the heart valves showed as well a proliferative reaction of the stroma and subendothelial cells giving rise to many cells with large

hyperchromic or vesicular nuclei and some multinucleate cells. The myocardium showed a fibrinoid degeneration with an endothelial infiltration. Only one heart was stained for bacteria and none were found. In a later paper Rinehart (1935) states that in one instance a large number of bacteria were seen associated with a lesion.

Joint changes were also described being again most marked in scorbutic infected pigs. These will not however be considered in this paper.

The organisms used were hemolytic streptococci obtained from spontaneous suppurative adenitis of pigs. An intradermal injection of 0.1 c.c. of a 24 hour glucose veal broth culture was given into the skin of the thigh.

FIG. 1.—The normal mitral valve of the guinea pig (x 60)

and local suppurative lesions developed. To protect the average pig from scurvy 4 c.c. of orange juice per day was needed. The biggest heart lesions were seen in infected pigs with subacute scurvy receiving 1-2 c.c. orange juice on alternate days.

Rinehart and Mettler considered that the lesions in the scorbutic infected pigs were essentially similar to those of human rheumatic fever.

Stimson, Hedley and Rose (1934) confirmed these results using hemolytic streptococci from human lymphadenitis but many negative findings were recorded. They also produced similar myocardial but no valvular lesions by intracardiac injection of scarlatinal streptococcal toxin in scorbutic pigs.

Schultz (1936a) has carefully repeated all Rinehart's work using the same organisms. He did not stain his heart sections for organisms.

Of his 24 control pigs 4 died from acute spontaneous hemolytic streptococcal infections and 5 of the uninfected ones showed pericarditis. Half the controls showed slight cardiac lesions, the commonest being subendothelial foci of mononuclear cells especially in the left ventricular papillary muscles.

His scorbutic pigs, which were never completely deprived of orange juice showed in about half no more than the controls. The rest showed diffuse valvular degeneration, with slight proliferation and occasional intense localised proliferation. Once only were there extensive changes including myo- and pericarditis.

His scorbutic infected pigs also never completely deprived of orange juice showed in addition to very severe local lesions at the site of injection the following: 1. Fibrinoid degeneration of the valves, the pericardium and the perivascular areas, the connective tissue becoming homogeneous, waxy and deeply eosinophilic. 2. A proliferative reaction of large mononuclear cells and lymphocytes around the degenerations. 3. No endocardial thrombi in spite of the destruction of the endothelium. 4. Rarely a myocarditis with necrosis of the muscle-fibres an increase in connective tissue cells and still more rarely a diffuse infiltration with small mononuclear cells and localised perivascular nodules of mononuclears and a few polymorphs. 5. A microscopic aortitis with mononuclear cells and a few eosinophils between the media and adventitia. Rarely intimal degeneration was present.

Some of the pigs were spontaneously infected with hemolytic streptococci and these showed more marked lesions than the pigs with induced infections.

Schultz considers that these lesions differ from those of human rheumatic fever in that no verrucous

endocarditis is seen, that the myocardial lesions do not closely resemble Aschoff nodules, and that they are few in number and are not distributed as are the multiple granulomata of rheumatic fever

Objects of the Experiments

The experiments to be described had five objects in view. First, to confirm the occurrence of lesions in infected scorbutic pigs, secondly, to attempt

FIG 2—Mitral valvulitis (scurvy + *S. viridans*) ($\times 50$)

to produce chronic lesions by the maintenance of chronic scurvy for as long as possible, thirdly, to see whether organisms were present in the heart substance, fourthly, to see whether the *Streptococcus viridans* was as efficacious as the hæmolytic streptococcus in producing lesions, and lastly, to see whether full doses of orange juice after infection would prevent or cure the lesions

Technique

Large pigs of over 300 g were used, as small ones perish very rapidly on a scorbutic diet. The basal diet was that of Rinehart and Mettler (1934), it contains adequate supplies of all vitamins except C, also sodium chloride and ferrous lactate. The diet and water were given ad lib. Measured rations of orange juice from fresh oranges were given with a fountain pen filler. The pigs were weighed weekly.

For the injections, 24 hour glucose beef broth cultures of human organisms, obtained from acute lesions, were used, and 0.2 c cm. was injected intradermally into the thigh. The hæmolytic streptococci were obtained from an appendix abscess and the green streptococci from an infected sinus. The hearts were opened, fixed and embedded so that, as far as possible, all valves were cut. Approximately every thirtieth and thirty first section was taken and stained with hæmatoxylin and eosin, and by the Gram Weigert method for bacteria.

It was only in the later stages of the investigation that the possible value of post mortem heart cultures was realised, and these were done in 13 pigs, but the injected organisms were never recovered and the inconstancy of the results demonstrated the well known difficulty of the technique.

Results

Weight changes—On the basal diet without orange juice, or with only 1 c cm. on alternate days, the pigs rapidly lost weight and died of scurvy in from one to three weeks. On 4 c cm. orange juice per day they gained weight steadily. On 2 c cm. orange juice on alternate days, scurvy was maintained in a chronic state.

Clinical changes—The scorbutic pigs showed the typical clinical signs—the head held on one side (the

scurvy face-ache position), paralysis of the hind limbs, loss of hair, loss of appetite, and hæmorrhage diarrhoea. Post mortem they showed subperiosteal, adrenal, and bowel hæmorrhages, and the characteristic heart changes. Only one pig showed any local reaction at the site of injection, an intradermal hæmorrhage.

Cardiac changes—The control pigs showed frequent subendocardial infiltrations with lymphocytes and endothelial cells, especially in the papillary muscles, and one showed a spontaneous pericarditis, a confirmation of the findings of Schultz (1936a). In the acute and chronic scorbutic pigs, whether infected or uninfected, the lesions were essentially the same, except that in the most chronic cases the hearts were considerably enlarged. Macroscopically, the mitral valves were usually thickened and puckered or actually nodular, sometimes with hæmorrhages into the nodules. The aortic valves were sometimes thickened and very occasionally nodular. The papillary muscles sometimes showed hæmorrhages. Microscopically, lesions were found at five sites: (1) the mitral valves, (2) more rarely, the aortic valves, (3) the auriculo ventricular junction (herein after called the A.V.J.), (4) the myocardium, between the muscle fibres, especially at the apex and in the papillary muscles, in the perivascular spaces, and in the auricle walls, and (5) the aorta. The cells in the lesions were polymorphs, endothelial cells, lymphocytes, and fibroblasts. In the acute lesions, polymorphs predominated, in the subacute and chronic, endothelial cells, lymphocytes, and fibroblasts. Giant cells were never seen. Most lesions showed interfibrillary and intercellular exudate, and a homogeneous appearance of the connective tissue. Small areas of calcification, as described

Note.—In all Tables P.V. infn. = Perivascular infiltration, I.M. infn. = Intramuscular infiltration, Inf. = Infiltration, and A.V.J. = Auriculo ventricular junction. When a pig is mentioned outside its own group the group number is placed before the pig's letter, thus Pig O of Group 1 becomes Pig 1O.

by Højer (1924) were occasionally seen in the myocardium

Mild degrees of congestion of the lungs and liver were seen in some of the acutely scorbutic pigs. Advanced degrees were however consistently seen in the chronic cases. This was not due to the method of slaughter as the pigs died naturally.

Vascular lesions in scorbutic infected pigs have been described by Menten and King (1935). They state that scorbutic pigs infected with diphtheria toxin or green or hemolytic streptococci show diffuse hyperplasia of the media of the arteries of the lungs liver spleen and kidneys. This is hard to estimate as unless the vessels are injected, the elastic tissue of the media contracts producing an apparent medial thickening. This was observed in the lungs and livers of control scorbutic and scorbutic infected pigs but one could not be certain that it was greater in the latter two groups. The coronary arteries of the scorbutic and scorbutic infected pigs frequently showed organised thrombi, but without evidence of infarction. Inflammation extending into the wall of the coronary artery was occasionally seen. Once complete hyaline degeneration of the media of the coronary artery was seen (Group 4 Pig C).

The pigs were divided into six groups:—

GROUP 1

SCURVY ALONE

The seventeen pigs in this group received the basal diet supplemented in eight cases by small doses of orange juice—never more than 3 c.c.m. on alternate days. Two pigs (B and D) having received 4 c.c.m. of orange juice on the twenty first day and 1 c.c.m. on alternate days from then on survived from 4 and 7 weeks respectively—the latter being killed. (The survival times are in all cases from the start of the experiment.) Four (A, C, L, and P) died within 2 weeks of starting the diet while the remaining eleven died within 4 weeks.

The macroscopic changes found were the typical scorbutic lesions, hemorrhages and congestion of the lungs (E and I) slight congestion of the liver (F, K, M, N, and O) and more marked congestion (O) fatty changes

FIG. 3.—Aortic valvulitis (subacute scorbutic + *Aeromonas*) ($\times 80$)

in the liver (G, K, M, O, P, and Q) and diffuse millary pyemic abscesses (J, L, N, O, P, and Q) affecting the liver spleen, kidneys and heart (J). The heart was enlarged in three (H, K, and I) and the mitral valve thickened and nodular in all except six (A, B, C, D, N, and O). The microscopic heart lesions are shown in Table I.

Organisms were present (though none had been injected) in 8 hearts; 4 of these (L, O, P, and Q) showed other evidence of autogenous infection—millary pyemic abscesses. In C they were large Gram-positive bacilli. In the rest they were Gram positive coccobacilli usually in pairs and sometimes showing polar staining (Fig. 6).

In some hearts there were intense polymorph reactions around the organisms. In others reactions and organisms were dissociated. The severest lesions were often in hearts entirely free from organisms (I, J and N).

Lesions somewhat resembling Aschoff nodules were present in the myocardium of L, P and Q and at the A.V.J. in L and Q (Figs 7, 9 and 10). These lesions were usually perivascular with intramuscular oxidate endothelial cells lymphocytes, fibroblasts, and a few

FIG. 4.—Mitral valvulitis (scurvitic + *Aeromonas*) ($\times 160$)

polymorphs, but no giant cells. Other myocardial lesions were two areas of necrosis 2 and 3 mm. across with an intense inflammatory reaction around but no organisms associated (J), perivascular polymorph infiltrations (J, Fig. 8) massive active inflammatory infiltration in the auricle (B, C, I, J, and Q) and large planes of endothelial cells, lymphocytes and some polymorphs distending apparently the ventricular lymphatic vessels (L). Organised thrombi in the coronary artery at the A.V.J. were present in N, O and P.

The mitral valves showed varying degrees of edema between the fibres oxidate hemorrhage and diffuse and localised cellular infiltration. In the diffuse infiltrations, the cells were endothelial sometimes whorled around a small blood vessel and lymphocytes. The localised infiltrations (D, F, I, N, and Q) showed a necrotic centre with a polymorph reaction around, with some endothelial cells and lymphocytes as well. The valve endothelium was never destroyed and platelet deposits were absent. A mass of fibroblasts on the auricular surface of the valve was present in M.

GROUP 2

SCURVY PLUS 8 HEMOLYTICUS

For the first 3 weeks the eight pigs in this group received basal diet only and all developed well marked clinical scorvut. From then on they were given 0.5 to 2 c.c.m. of orange juice on alternate days according to the severity

TABLE II—Group 2

of their condition. G and H survived for 11 weeks. A for B and D for 6 and the rest for 4 weeks. After 31 weeks 0.2 c.c.m. of a 24 hour culture of *S. hemolyticus* was injected intradermally. No local lesions developed.

The macroscopic changes found were the typical scorbutic lesions, acute mediastinitis (B and D) congestion of the liver and cardiac enlargement (G and H) the two

pigs which survived for 11 weeks), puckered nodular mitral valves with hemorrhages (D, E, F, G, and H), and papillary hemorrhages (D and F). The microscopic heart lesions are shown in Table II.

Organisms were present in four in considerably greater numbers than in the hearts of Group 1. In three the organisms were Gram positive cocci in pairs or short

FIG 5—Gram positive cocci in tip of mitral valve (scurvy + *S. hemolyticus*) ($\times 250$). A dense mass of organisms is seen on the extreme left.

chains, morphologically identical with the injected streptococci. The remaining organisms were Gram positive coccobacilli in pairs showing polar staining, similar to those found in Group 1. The mass of cocci in the valve of D is shown in Fig 5. In C, cocci were present both in the folds of the valve surface and in the valve substance.

Small polymorph masses were present in the ventricular muscle of B, D, and F. B and D showed large acute inflammatory infiltrations in the auricular muscle. The mitral valves showed acute inflammatory nodules in D, E (Fig 4), and F, while B and C showed diffuse infiltration only.

GROUP 3

NORMAL DIET PLUS *S. HEMOLYTICUS*

The three pigs in this group received the basal diet plus 4 c.c.m. orange juice daily. In the 8 weeks of the experiment their weights steadily increased from an average of 270 g. to an average of 490 g. After 3½ weeks, 0.2 c.c.m. of a 24-hour culture of *S. hemolyticus* was injected intradermally. No local lesions developed and the pigs continued to gain weight. After slaughter, one pig showed a chronic adhesive pericarditis, such as is commonly seen in controls (Schultz 1936a), and an organised thrombus in one coronary artery, but no organisms. There was no myocarditis or valvulitis. The other two pigs showed no abnormalities.

D	+	+++	-	+++	-	+++	+++	++

GROUP 4

SUBACUTE SCURVY PLUS *S. HEMOLYTICUS*

For the first 12½ weeks the pigs received 1 to 2 c.c.m. orange juice on alternate days. Hemolytic streptococci being injected as before after 4 weeks. A died after 9 weeks and B and D after 12 weeks. C was then given 4 c.c.m. orange juice daily and it gained weight steadily for the next 5 weeks. It was then killed.

Post mortem A and B showed typical scorbutic lesions. The liver of C was very fatty (cf. Group 5). Those of A, B, and D had a typical nutmeg appearance, and histologically they showed intense congestion with fatty change. The lungs of B and D also showed marked congestion on histological examination. In all, the heart was greatly enlarged and the mitral valves thickened and nodular. In D, the aortic valve was nodular. The microscopic heart lesions are shown in Table III. The organisms in A were Gram positive diplococci and in C and D Gram positive coccobacilli in pairs with polar staining.

Lesions somewhat resembling Aschoff nodules were present at the AVJ of D. Organised thrombi were present in the coronary arteries of C and D. The valvulitis was localised in A, C, and D. The aortic valve of D showed an inflammatory mass composed of polymorphs, lymphocytes, and endothelial cells, the valve endothelium being intact (Fig 3). C showed an inflammatory reaction in the intima and adventitia of the aorta.

GROUP 5

SCURVY PLUS *S. HEMOLYTICUS*, FOLLOWED BY NORMAL DIET

The four pigs in this group received the basal diet only for 4 weeks. Organisms were then injected as in Groups 1, 3, and 4, and thenceforward the pigs received 4 c.c.m. orange juice per day. All recovered from their scurvy and gained weight continuously for the remaining 15 weeks of the experiment. They were then killed. None showed signs of scurvy post mortem. The livers were very fatty; the hearts were all slightly enlarged, and the mitral valves were all nodular. The microscopic heart lesions are shown in Table IV. In C, the ventricular lymphatics

FIG 6—Gram positive coccobacilli with polar staining in mitral valve (scurvy) ($\times 800$).

vessels were filled with cells as in 11L. Massive inflammatory infiltration of the auricle, mainly with endothelial cells, was present in C. The valvular infiltration was diffuse in A, B, and C and localised in D. The valvulitis was endothelial and in A, B and D many fibroblasts were present. The valve of C contained an immense hemorrhage. Acute inflammatory masses in the aorta were present in B (media) and C (adventitia).

GROUP 6

SCURVY PLUS *S. VIRIDANS*

The four pigs in this group received the basal diet for 3½ weeks. They were then injected intradermally with 0.2 c.c.m. of a 24-hour glucose beef broth culture of

Streptococcus viridans. B developed a haemorrhage at the site of injection. The others showed no local lesions. From then on the pigs received 2 c.cm. orange juice on alternate days. B died after 4 weeks. D after 5 and A after 6. C gained weight on this dose of orange juice so it was reduced first to 1 c.cm. then to 0.5 c.cm. on alternate days. It died after 13 weeks.

FIG. 7.—Aschoff like area in myocardium (scurvy) ($\times 65$)

Post mortem A, B, and C showed typical scorbutic changes. C showed dilated auricles, congested lungs, and a nutmeg liver; the congestion and fatty change being confirmed histologically. A showed slight congestion of the liver on histological examination only. D showed millary abscesses of the liver and spleen. All hearts showed puckered nodular mitral valves. The microscopic heart lesions are shown in Table V. Gram positive diplo-

group of organisms was definitely not streptococcal. The two pigs which lived in subacute scurvy for the last 7 of their 11 weeks both showed enlarged hearts and very congested livers.

Intradermal haemolytic streptococcal infection in non-scorbutic pigs does not result in the characteristic heart lesions seen in scorbutic pigs.

Subacute scurvy plus intradermal haemolytic streptococcal infection leads to heart lesions similar to those seen in acutely scorbutic infected pigs, but the hearts of these pigs were large and the livers and lungs showed much venous congestion. The livers also showed fatty changes. A chronic congestive cardiac failure appears to have been produced. The one pig which spent the last 5 weeks of its life on an adequate diet showed no venous congestion and although there was no antemortem debility—it was killed in apparent good health—its mitral valve contained organisms.

A full antiscorbutic diet started immediately after intradermal haemolytic streptococcal infection did not cure the cardiac lesions. These showed evidence of chronicity in the absence of polymorphs and the abundance of endothelial cells, lymphocytes and fibroblasts. The full diet appeared to free the valves from organisms and prevent the development of congestive failure.

Scurvy plus intradermal Streptococcus viridans infection results in cardiac lesions which do not differ from those seen in scorbutic pigs with or without extraneous haemolytic streptococcal infection. Two hearts showed organisms morphologically identical with those injected, but the second also showed diplo-cocci bacilli with polar staining. Once again subacute scurvy was associated with passive venous congestion.

TABLE V.—Group 6

Pig	Myocardium			A V J		Mitral valve.		
	P V Infa	I M Infa	Organisms	Infa	Organisms	Edema	Infa.	Organisms
A	—	++	—	+	—	+++	+++	—
B	+	++	++	+	—	+	+	—
C	+	++	—	—	—	+	++++	+
D	+++	+++	—	+++	—	+++	+	—

cocci were present in the myocardium of B associated with a small polymorph abscess. The valve of C (Fig. 2) contained two short chains of streptococci and a few Gram positive coccobacilli in pairs with polar staining. D showed Aschoff like areas at the A V J. The valvular infiltration was localized in A and C and in C—the most chronic case—endothelial cells and fibroblasts predominated.

Discussion

The findings in the six experimental groups are summarised below.

Scurvy alone—In the absence of extraneous infection scurvy leads to valvulitis and myocarditis with acute and subacute inflammatory foci. Gram positive cocci or bacilli were present in half the diseased hearts but many of the severest lesions showed no organisms.

Scurvy plus intradermal haemolytic streptococcal infection leads to heart lesions differing in no essential way either in incidence or histology from those seen in scorbutic pigs not so infected. Two thirds of the hearts showed organisms, and they were more numerous than in the scorbutic hearts—but one

FIG. 8.—Intravascular infiltration (scurvy) ($\times 160$)

CAUSE OF THE CARDITIS

The carditis may be due to scurvy alone, to scurvy plus autogenous infection, or to scurvy plus extraneous experimental infection. Since the lesions were as common in scorbutic pigs as in scorbutic experimentally infected pigs the first or second explanation must be true though this does not exclude the third possibility.

The lesions occurred in 16 pigs in which no organisms were found. But as only about 60 of the 600 sections from each heart were examined it is quite possible that organisms were missed. Organisms were present in 8 out of 17 scorbutic pigs with lesions and in 9 out of 13 scorbutic experimentally infected pigs with lesions. Further organisms were present

in much greater numbers in the second group. Of the scorbutic pigs, 1 showed Gram positive bacilli, while 7 showed Gram positive coccobacilli with polar staining. Of the scorbutic experimentally infected pigs, 5 showed Gram positive cocci in pairs or chains, while 4 showed Gram positive coccobacilli with polar staining.

If the lesions represent the response of the scorbutic heart to infection, it appears that the infection is in no way specific. Bacilli and coccobacilli are just as, if not more, important than streptococci.

The frequent dissociation of lesions and organisms suggests that they may be a non-causative secondary infection. The occurrence of organisms in a recovering pig (4C) is against their being a terminal infection.

Conclusions—The one specific factor associated with the cardiac lesions is scurvy. Extraneous infection increases neither the incidence nor the severity of the lesions. The lesions sometimes contain organisms, even in pigs not experimentally infected. Organisms are more frequently seen after extraneous experimental infection. The infection does not appear to be a terminal one, but it may well be a secondary phenomenon of no importance.

COURSE OF THE DISEASE

All the 6 pigs with subacute or chronic scurvy showed considerable congestion of the lungs and liver, with fatty changes in the liver. Of the rest, 1 showed moderate hepatic congestion and 6 slight. Apparently the scorbutic carditis, if allowed to become chronic, results in congestive cardiac failure.

Clinical cure of scurvy in 5 pigs did not result in the disappearance of the cardiac lesions. It seems that once the heart is damaged, vitamin C will not

framework of the heart and its coverings, and other parts of the body. Experimental rheumatic fever should therefore show not only Aschoff's nodules but also these nodules characteristically distributed. Thus scorbutic carditis cannot claim to do

FIG 10—Aschoff like area at auriculo-ventricular junction (scurvy) ($\times 400$)

Myocardial lesions—The commonest sites of inflammation in the scorbutic pigs were at the base of the interventricular septum and the origins of the papillary muscles, both common sites for Aschoff's nodules. But in rheumatic fever the nodules are also distributed diffusely throughout the ventricular myocardium, and this was never seen in the pigs.

Lesions bearing some morphological resemblance to Aschoff's nodules were seen in 5 hearts (3 in the myocardium and 4 at the A V J). These lesions were usually perivascular or near arterioles. They showed much intramuscular exudate, in the early stages a polymorph reaction, and in the later stages endothelial cells, lymphocytes, and fibroblasts. Giant cells were never seen. But many of the myocardial lesions bore no resemblance whatever to Aschoff's nodules, for example, the huge areas of necrosis in 1J, the frequent small polymorph abscesses in the ventricles, and the massive polymorph infiltrations in the auricles. The infiltration of the lymphatic vessels with cells (1L and 5C) is sometimes seen in rheumatic carditis but is not specific (Grant 1936). Bacteria in rheumatic carditis are, to say the least, rare. Klinge and McEwen (1932) made complete serial sections through rheumatic hearts. Bacteria were occasionally seen, but their position and polymorphism suggested that they were of no aetiological significance.

Valve lesions—The valves attacked in the scorbutic pigs were the mitral and rarely the aortic. In rheumatic fever the aortic valve is attacked in a somewhat higher proportion of cases. The valvulitis in the pigs was similar to the rheumatic valvulitis but polymorphs were perhaps more abundant. No blood vessels with whorling of the endothelial cells around, such as are seen in rheumatic valvulitis (Coombs 1924), were common. Vegetations were, however, never seen. But very rarely, rheumatic valvulitis occurs without the formation of vegetations (Grant 1936). The valvulitis is the essential feature and the vegetations are secondary. Organisms are not seen in rheumatic valvulitis.

FIG 9—Fulgured view of Fig 7 ($\times 400$)

cure it though it does prevent the development of congestive failure.

RELATION OF LESIONS TO RHEUMATIC CARDITIS

Grant (1936) has pointed out that there is nothing specific for rheumatic fever in the tissue reaction seen in the heart. All the cells seen in the Aschoff's nodules are met with in infections from other causes, for example the large mononuclear and multinuclear cells are seen in the vegetations of subacute bacterial endocarditis. But in no other disease do we find these small foci distributed throughout the fibrous

scorbutic valvulitis they are frequently present sometimes in large numbers. Yet the valvulitis bore no morphological resemblance to human bacterial endocarditis.

Aortic lesions.—The aorta in the scorbutic pigs sometimes showed polymorph infiltrations. These are sometimes seen in human rheumatic carditis (Coombs 1924 Shaw 1929).

Conclusions.—The lesions in scorbutic carditis are those of non-specific inflammation. In so far as rheumatic carditis shows non-specific inflammation they can be said to be similar. But that is all. The scorbutic lesions often bear no resemblance to rheumatic lesions and bacteria are frequently present in the scorbutic lesions. However neither clinically nor morphologically does scorbutic carditis resemble human bacterial endocarditis.

RHEUMATIC CARDITIS AND VITAMIN C

Rinehart (1935) has pointed out that scurvy and rheumatic fever both show joint lesions, a degeneration of the collagenous tissues and hemorrhagic manifestations. Geographical, social, environmental and seasonal incidences show no convincing correlation. Warner, Winterton and Clark (1935) found no lack of fresh fruit and vegetables in rheumatic children but, at Christ's Hospital, an increase in consumption was associated with a fall in rheumatic fever.

Years	1918-22	1923-7	1928-32
Consumption of fresh fruit and vegetables per day	0.31 lb	0.39 lb	0.41 lb
Cases of rheumatic fever	19 (3.4%)	9 (1.1%)	6 (0.75%)

But in the first five year group the children had no fresh butter, less total protein and fat and more carbohydrate.

Perry (1935) examined the vitamin-C reserves in 5 active and 6 quiescent children and concluded that lack of vitamin C is not an important factor in the cause of acute rheumatism though mild degrees of this deficiency are not uncommon in rheumatic children.

Sendroy and Schultz (1936) found an apparent ascorbic acid deficiency in 8 out of 13 rheumatic children but in only 2 of these could it be ascribed to a poor diet. The others vomited the test doses or failed to absorb them. They considered that their results did not support the C lack hypothesis.

Schultz (1936b) found that large doses of ascorbic acid reduced the capillary fragility in 28 children with old rheumatism but did not reduce the incidence of recurrent rheumatic manifestations. This seems to show that the rheumatic children were not completely saturated with vitamin C.

Abbasy Hill and Harris (1930) using 107 active rheumatics, 88 convalescent rheumatics, 64 controls, 42 cases of active and half active surgical tuberculosis and 46 quiescent cases found a striking decrease in vitamin C excretion in the active and convalescent rheumatics and in the cases of active tuberculosis. The cases of quiescent tuberculosis gave normal excretions. Further it was extremely difficult to saturate the rheumatic children with vitamin C. They conclude that there is in rheumatic fever a greatly increased metabolic use of and need for vitamin C. They accordingly recommend large amounts of vitamin C both therapeutically and prophylactically.

In the unlikely event of there being any direct relation between human rheumatic fever and the scorbutic carditis of pigs the results described in this paper would suggest that vitamin C is of the greatest prophylactic value but of less use therapeutically.

Once the scorbutic carditis has been produced cure of the scurvy has no effect on the appearance of the heart lesions though it does prevent the development of congestive failure. Further a mild degree of scurvy (plus infection) is enough to produce the carditis so that the absence of frank scurvy in rheumatic children does not exclude the possibility of a relationship.

Summary

1 Guinea pigs suffering from scurvy show in their hearts valvulitis, myocarditis and occasionally pericarditis often associated with Gram positive organisms even when none has been injected.

2 The lesions are commonest in the mitral valve, the auriculo-ventricular junction, the perivascular areas in the myocardium, and the papillary muscles.

3 In the acute lesions polymorphs predominate in the chronic lesions endothelial cells, lymphocytes and fibroblasts. Exudate is usually present. Giant cells and vegetations are never seen.

4 The lesions resemble those seen in rheumatic carditis only in that they are both a diffuse non-purulent carditis without gross valvular vegetations.

5 The intradermal injection of hemolytic or green streptococci in scorbutic guinea pigs does not increase the incidence or severity of the lesions but does increase the incidence with which organisms are found in the heart.

6 Organisms are found in the mitral valve, the auricular and ventricular muscle and the auriculo-ventricular junction. They are Gram positive bacilli, coccobacilli in pairs showing polar staining and when these have been injected, streptococci. They were not recovered by heart culture. They are usually but not always associated with lesions but many of the largest lesions contain none. This autogenous or extraneous infection of the heart is probably not terminal but may be secondary and unimportant in causing the lesions.

7 Infected guinea pigs with mild subacute scurvy show similar lesions.

8 Infected guinea pigs kept in a state of subacute scurvy for a considerable time develop congestion of the lungs and liver, the latter having a nutmeg appearance.

9 Once the heart lesions have developed curing the scurvy will not remove the lesions though it does prevent the development of congestive failure.

I have to thank Prof. S. J. Cowell, Prof. O. L. T. J. Wesslow and Dr. J. Bamforth for their criticism and encouragement and A. James and L. J. Lewis for their help with the animals and the histological work. The Marmite Food Extract Company kindly supplied yeast for the animals diet free of charge.

TUBERCULOUS GLANDS OF THE NECK IN CHILDREN

RESULTS OF SURGICAL TREATMENT

By SIR LANCELOT BARRINGTON-WARD, K C V O,

Ch M, F R C S Edin, F R C S Eng

SENIOR SURGEON, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, SENIOR SURGEON, ROYAL NORTHERN HOSPITAL

RECENT articles and correspondence in the medical journals have painted a gloomy picture of the surgical treatment of tuberculous glands of the neck. Dr Brian C. Thompson, district tuberculosis officer, seems to have been peculiarly unfortunate in his experience and has condemned the radical surgical treatment wholeheartedly (*Lancet*, 1936, 1, 946, *Brit med J* 1936, 2, 584). After personal observation of 44 cases, representing 55 radical operations, he found that there was a gross, palpable, local recurrence in 50 cases. Of 36 patients, 18 had a persistent discharging sinus. Of 43 cases, in 21 the scars were bad. Results such as these are grievous indeed and would certainly condemn the surgical treatment of tuberculous glands of the neck, if this were the general experience of surgeons accustomed to deal with large numbers of these cases.

These findings were so completely at variance with my own experience that I determined to check my position and see exactly what my results had been at the Hospital for Sick Children, Great Ormond-street, over a period of years. In a children's hospital with an age limit of 12 a prolonged follow up is difficult, but with the aid of an efficient almoner's department I was able to trace 95 cases from a consecutive list of 133 radical operations. Of the 95 cases traced, I have personally examined 89. The patients were examined in my out-patient clinic and the visiting post-graduate and undergraduate students served as a jury in assessing the cosmetic and general results of the operation.

In estimating the success of any method of treatment the essential points to be determined are (1) the mortality, (2) the cure of the disease, (3) any deformity due to the operation, structural damage, and scarring, (4) the time taken to effect a cure. The results in this series were as follows—

(1) *Mortality*—There was no operative mortality. Ninety-four of the 95 patients traced were alive and well. One patient had died three years after the gland operation from mastoiditis and streptococcal meningitis. It has been suggested that generalised tuberculosis some times follows the excision of tuberculous glands of the neck. I have never seen this, but I have notes of 2 cases in which scraping of a tuberculous abscess was followed by tuberculous meningitis.

(2) *Cure of the disease*—Only 1 case required any further treatment. Eleven patients had slightly enlarged glands in a different part of the neck from the original operation, but the patients were not aware of them. They were all in perfect general health.

(3) *Deformity*—This may arise from nerve injury or from scarring. In no case was there any injury to any nerve. As to scarring as critical an attitude as possible was adopted in estimating the amount of deformity. It was decided that *good* should mean a scar that was invisible or could just be detected on close inspection. *Fair* should denote a scar that could be seen but not be considered a disfigurement. Such a scar would be in the line of one of the neck creases, but a little broad or a little thickened. *Poor* should include the others—scars (puckered, irregular or broad) not in one of the natural creases, scars that made it at once apparent that an operation had been performed on the neck. Many of the patients were photographed as a record and these

photographs can be inspected by anyone interested. Examples of what was judged good, fair, and poor.

Good—Of the 65 patients considered good, in 26 a scar was practically invisible.

Fair—20 patients.

Poor—The 4 patients in this category had suffered from severe skin infection and sinuses before commencing operation.

(4) *Time taken to effect a cure*—The average stay in hospital was 22 days. Three had had a discharging sinus after operation.

DISCUSSION

In the consideration of these results, it must be remembered that the majority of the glands were caseous, 30 of them were complicated by an abscess and 10 by sinuses—the result of no treatment or treatment elsewhere. Extensive involvement of the skin makes a good cosmetic result difficult. There were nearly all instances of primary pharyngeal infection and therefore presumably bovine in origin. The tonsillar gland was usually the first infected, a removal of the tonsils formed part of the treatment. All the patients were children. In these respects this series may differ from patients of all ages. Tuberculosis dispensaries, where general infection and infection by the human bacillus may be more prevalent.

It is not my intention in this short paper to criticise closely alternative methods of treatment. Sympferin iod, various tuberculin, X rays and radium actinotherapy of different kinds have their convinced supporters who will probably remain convinced of their efficacy. The variety alone of the therapeutic measures indicates some weakness in position. Moreover, there are certain obvious disadvantages. Non-surgical treatment may have to be prolonged for months or years. In this series treated by dissection the average stay in hospital was 22 days, and the patients could then be considered cured. The presence of discharging sinuses in ambulatory patients cannot be considered healthy for the community. It would not be tolerated in the circles from which private patients are drawn. After dissection only 3 of 89 patients had a discharge from the wound after operation, which persisted a few weeks in one case, 2 months in another, and 6 months in the third.

SURGICAL MANAGEMENT

The surgical management of a tuberculous gland in the neck should be, in brief, as follows—

When the patient is first seen, a thorough search is made for any focus of infection. From the anatomical situation of the gland, it is usually possible to deduce the portal of entry—tonsils, adenoids, scalp, teeth, or ears—and the appropriate treatment, if necessary, is instituted. Rest is enjoined in mild cases by splinting the neck, in severer cases by recumbency. A convalescent home may be desirable. Every measure is taken to improve the general resistance of the patient. The glandular enlargement is watched and many will recede and disappear under this treatment. The simple gland, due to a septic infection alone, will certainly subside. If the gland persists after 3 months of general treatment, or if at any time it shows signs of softening or enlargement, it should be excised. The removal of a tuberculous gland intact leaves an invisible scar and terminates the illness. If the patient is seen for the first time with the glands caseous, with deep or superficial abscess formation, excision is still the best treatment. Incision and aspiration lead to infection of the skin and a sinus in most cases. A superficial abscess, provided that the skin is not too widely involved, is no contra-indication to operation.

Removal of all the underlying glands from which the abscess has arisen leads to a speedier cure. All the glands in the affected area can and should be dissected out. If every visible gland is removed there will be no local recurrence. It has been often remarked that the operation is not one to be undertaken lightly and should not be relegated as so often in the past to a now house surgeon for a minor surgical exercise. It requires good anaesthesia, good light and adequate assistance. Under these conditions the surgical removal of tuberculous glands of the neck by dissection is one of the most satisfactory operations in surgery.

I am greatly indebted to Mr John Semple, F.R.C.S. surgical registrar to the hospital for the great trouble he has taken in collecting these cases and checking my observations.

THOROTRAST AS A CONTRAST MEDIUM

A CASE REPORT

By CLAUDE ELMAN, M.D., M.R.C.P. Lond.

ASSISTANT PHYSICIAN TO QUEEN MARY'S HOSPITAL, STRATFORD
PHYSICIAN TO THE MARLBOROUGH STREET HOSPITAL FOR
DISEASES OF THE CHEST, LONDON AND

ELIZABETH HAWORTH, M.R.C.S. Eng., D.M.R.E.

RADIOLOGICAL ASSISTANT AT THE LONDON HOSPITAL

We have observed the use and effects of Thorotrast in a case in which a detailed post-mortem examination was made and we think it may be useful to place our investigations on record.

Thorotrast is absorbed by the reticulo-endothelial system and is radio opaque so that it makes the liver and spleen visible on radiography. It is described by the manufacturers as a highly dispersed thorium dioxide sol containing 25 per cent of thorium dioxide and miscible under any conditions with body fluids without flocculence.

CLINICAL RECORD

The patient was admitted to Queen Mary's Hospital, Stratford, on Oct 5th 1934. His age was 58 and he had been quite well until June 1934, when he had an attack of pleurisy for which he had a week in bed. Six weeks later he thought he had a swelling in the right upper abdomen. His appearance was fairly healthy, but his speech and mental processes were slow. His teeth were carious and there was a good deal of pyorrhea. The tonsillar glands were enlarged. The lungs nervous system and heart showed no abnormal physical signs apart from frequent extrasystoles. The liver however was greatly enlarged reaching to within one inch of the umbilicus, and there were three elastic swellings palpable near the lower margin. No free fluid was apparent in the abdominal cavity. In the out patient department a tentative diagnosis of secondary malignant disease of the liver had been made, but a barium-meal examination performed on Sept 20th did not indicate malignant disease of the stomach.

Pathological investigations.—A blood count (Oct 7th) showed 13,200 white cells per c.mm. with polymorphs 61 per cent, lymphocytes 20 per cent, monocytes 5 per cent, eosinophils 1 per cent, and basophils 1 per cent (count of 300 cells). There was moderate anisocytosis (microcytosis without megalocytosis) and some pallor of the red cells; also occasional poikilocytosis and polychromasia. The blood Wassermann reaction was negative and the complement fixation test against echinococcus antigen was also negative. An examination of the urine (Oct 10th) showed albumin +, sugar 0. There were a few white cells and epithelial cells, but no casts or crystals. *B. coli* was grown in culture. A test for occult blood in the faeces was positive.

Course of illness.—On Oct 13th the patient developed some coryza with pyrexia. For the next fortnight his condition remained about the same with a slight rise in

the evening temperature. It was then decided to give 75 c.cm. of thorotrast in three doses of 25 c.cm. on alternate days. No ill effects were noticed after the first injection on Oct 20th but after the injection on Nov 2nd the patient complained of headache and the temperature rose to 101° F. in the evening. Various X-ray photographs were taken on Nov 1st 3rd 5th and 6th. On Nov 13th a barium-meal radiogram showed a large growth of the stomach extending into the liver near the cardia. The patient's condition on the 17th was now changing for the worse and on the 18th he had a hæmatemesis of four ounces. On Nov 19th he had obvious melenæ. From that time he became progressively weaker and he died on Dec 3rd.

Summary of X-ray reports.—As already stated a barium meal examination on Sept 20th produced no certain evidence of carcinoma of the stomach. On Oct 10th the oesophagus and large bowel were also examined without positive result. In making the thorotrast investigations the technique adopted was that described by Porritt (1934). The full course of 75 c.cm. was given. Twenty-four hours after 25 c.cm. the liver shadow appeared well defined and already showed large circular non-opaque

FIG. 1.—Section of liver with secondary growth. The right part of the section shows the liver tissue and the stained Kupfer cells packed with thorotrast. The tumour cells on the left contain no thorotrast. (x 100.)

areas. Maximum definition of these areas was attained on the films taken 72 hours after 75 c.cm. had been injected. These appearances were taken to be conclusive of metastases in the liver. On Nov 13th the stomach was again investigated and the film now gave convincing evidence of a new growth of the cardiac end.

POST-MORTEM FINDINGS

Large ulcerated growth in the stomach perforating into the "lesser sac" of the peritoneum with localised peritonitis. Massive secondary growths in the liver and gastrophrenic lymph glands. Small secondary growths in the kidneys.

On section the growth proved to be a spindle-celled sarcoma of uniform structure throughout both in the primary and in metastases. Thorium was present in the reticulo-endothelial cells of all tissues and was almost confined to these cells except for a little in some endothelial cells and fibroblasts in inflamed tissue (lesser sac). The Kupfer cells of the liver showed the largest amount of thorium (Figs 1 and 2) with the spleen bone marrow and lymph glands following in that order. There was almost none in the liver cells and none in the tumour cells (Fig. 2). In the lungs thorium was present only in one of the two phagocytes in the alveolar lumina.

There was much proliferation of the Kupfer cells of the liver and of the reticulo-endothelial cells of the spleen. A few of the thorium-containing cells in the latter were apparently disintegrating.

DISCUSSION

The immediate after-effects of thorotrast in this case are difficult to assess since the patient was gravely ill before the injection but at least no important immediate harm was done. The radiograms obtained with it made the diagnosis of secondary malignant disease definite although the diagnosis would have been established in any case by the second barium meal. But where the clinical evidence of secondary growth from a primary stomach

or bowel neoplasm is non-existent, thorotrast would be useful.

The pathological evidence in this case confirms previous observations that the reticulo-endothelial system is the main site of storage of thorotrast. Five weeks after injection the substance was present in only trifling quantities in other tissues and at that date the amount even in the liver parenchyma was very small. The histological picture described suggests some damage to cells of the system together with some proliferation. The rate of elimination is obviously extremely important in considering the possible risks in the use of thorotrast. The present case can do no more than indicate that apparently very little elimination occurred in five weeks. Examination of the various possible excretory tissues revealed scarcely any thorium. The largest amount was

FIG 2—Section of liver showing Kupfer cells distended with thorotrast. The actual liver cells contain no thorotrast ($\times 425$)

found in the lungs, but even here the quantity was very small. If this be the main or only route of excretion it seems likely that complete elimination would take a very long time.

CONCLUSIONS

(1) In the single case recorded thorotrast was useful for the radiological demonstration of a gross hepatic lesion. (2) It produced no serious immediate reaction. (3) On the other hand the post-mortem findings suggested damage to the reticulo-endothelial system and very slow elimination. (4) We are not satisfied therefore that the use of this substance is desirable.

We are indebted to Dr John Gray (late director of pathology and Lylo Research Scholar at Queen Mary's Hospital, Stratford) for the pathological examinations and photomicrographs.

ACUTE DACRYOADENITIS

By B. ROGOL, M.B. Dublin

HOUSE SURGEON, PRINCESS LOUISE KENINGTON HOSPITAL FOR CHILDREN, LONDON

INFLAMMATION of the lacrimal gland, whether acute or subacute, is so extremely rare that I am recording the following case—

A girl aged 8 presented herself at the casualty department of the Princess Louise Hospital on Jan. 25th, 1937, with pain and swelling in the region of the left eye. Two days previously the parents had noticed that the upper lid of the left eye was slightly swollen although the child herself did not complain. This state continued until the following night when the child did not sleep owing to intense pain. In the morning as the swelling was

considerable and the pain persisted, she was brought to hospital. Both left eyelids were swollen and it was almost impossible to open them because of tenderness on pressure, especially over the outer half of the upper lid. The palpebral conjunctiva was slightly injected and there was some chemosis. The temperature was normal. The parents refused to allow the child to be admitted to hospital so she was treated in the out-patient department by instillation of Argyrol 25 per cent twice daily and frequent hot fomentations. After two days the swelling was reduced sufficiently to allow of more thorough examination. By this time the swelling appeared to be greatest in the outer half of the upper lid. There was tenderness on pressure over this area and a nodular mass could be felt projecting from beneath the outer angle of the orbit. With the eye open the edge of this mass could be seen. Chemosis was now conspicuous and movements of the eye itself were limited in all directions. There was no proptosis. A diagnosis was made of acute dacryoadenitis.

The parents now allowed the child to be admitted to hospital (Jan. 27th). A swab was taken and the Koch-Weeks bacillus found. Argyrol was discontinued, hot fomentations were applied every two hours, and the eye washed regularly with weak saline. This was continued for four days without much improvement. The treatment was then changed to instillation of argyrol 25 per cent twice daily, hot fomentations, and washing with oxy-cyanide of mercury 1 in 10,000 every four hours. After several days on this routine there was definite improvement. Pain and tenderness disappeared though the gland was still palpable. The fomentations were then discontinued and the eye only bathed with oxy-cyanide of mercury three times daily till Feb. 7th when the patient was discharged with no signs or symptoms. The temperature had remained normal throughout. The condition thus resolved within a fortnight of its onset without suppuration.

I am indebted to Mr A. E. A. Loosely, ophthalmic surgeon to the hospital, for permission to publish this case.

ORAL ADMINISTRATION OF STOVARSOL IN CASES OF NEUROSYPHILIS CERTIFIED AS INSANE

By R. PAKENHAM WALSH, B.M. Oxon., D.P.M.
ASSISTANT MEDICAL OFFICER AND

A. T. RENNIE
LABORATORY TECHNICIAN, COUNTY MENTAL HOSPITAL,
LANCASTER

VERY little has been written about the use of Stovarsol by mouth in the initial treatment of general paralysis of the insane; only 3 cases have been recorded (Cady and Aitken 1933), and in these a mercury preparation was also given. Promising results in this disease, however, following injections of the sodium salt, have been described by several authors, notably Sézary and Barbé (1930, 1936).

Stovarsol first discovered by Ehrlich, is a pentavalent arsenical which can be given in tablets by mouth, or in injection of the sodium salt. It is a preparation of 3 acetvlamino 4 hydroxyphenylarsonic acid which is made in this country by Messrs May and Baker. Other preparations of the same compound are sold in England under the synonyms of Kharophen (Burroughs Wellcome), Orarsan (Boots) and Spirocid (Bayer). It is also referred to as acetarsol (British Pharmacopoeia Addendum 1935), Ehrlich 594, Fournieu 190, Acetarsonic Goul, Acetphenarsone, Orarsol, Orarsan, Paroxil, Stovarsol, Dynarsan, Arsaphen and Ovaloid. We give it the name stovarsol here because the May and Baker preparation was used throughout, having been supplied gratis by the makers for clinical trial.

In the title of this paper caution has been taken in the definition of the disease concerned. A certified

mental patient admitted to a mental hospital exhibiting the characteristic serology of general paralysis may still be suffering from the meningovascular condition. Biggart (1936) states that he has found 20 per cent of cases diagnosed as paresis to be examples of cerebro spinal syphilis. This distinction is of importance when estimating the value of a new chemotherapeutic remedy in alleged cases of general paralysis, since one must bear in mind the readiness with which meningovascular cases respond both clinically and serologically to ordinary antisyphilitic treatment. In fact it has even been suggested that a serological response to such treatment excludes a diagnosis of general paralysis (Greenfield and Carmichael 1925).

In the present investigation all the patients had been certified as insane, and the predominance of mental symptoms indicated that the lesions were parenchymatous rather than interstitial. The cerebro spinal fluid changes moreover, provide striking evidence of the antisyphilitic value of an oral remedy, whatever the exact nature of the pathological lesions may have been.

Owing to the small number of cases in this series

and the short periods of time over which the treatments extended, this paper is presented mainly as a laboratory report, the clinical results being only briefly indicated in the Table.

COMMENT

Stovarsol given by mouth, if its action could be proved, would be an ideal remedy in neurosyphilis because it is so easy to administer, especially to out patients. On the other hand, several toxic effects may be produced, requiring the use of calcium thiosulphate (McLachlan 1933) as an antidote, and this had to be given on a few occasions in the above series. The symptoms produced, however, are dramatic and unlikely to escape the notice of the nursing staff, whereas the insidious onset of blindness sometimes observed with Tryparsamide, is a rare complication (Szárv and De Font Réaulx 1935; Szárv and Barbé 1932). Strict attention to dosage probably does much to prevent ill effects, and the scheme adopted here was to give the drug only on alternate weeks, the number of tablets given daily being regulated approximately by the body weight. Thus patients weighing 11 st, 9 st, and 7 st would

receive 5 4 or 3 tablets (each of 4 grains) respectively. Slight variations of this scheme became desirable when there were complications, but in only two cases did it become necessary to stop the treatment altogether for this reason. As a rule however the stovarsol was stopped on account of malarial inoculation. In some cases it was used later to terminate the induced fever but its action was found to be less prompt than that of quinine.

A comparison of the data set out in our Table with those from a control series of untreated cases was impracticable, but two papers (Barbé and Sézary 1924 Targowla 1924) on the spontaneous modifications of the cerebro-spinal fluid in general paralysis make it evident that consistent changes towards the normal must be attributed to the treatment. Moreover the results compare very favourably with the laboratory reports following treatment with malaria (Grant and Silverston 1924) or trypanamide (Lorenz and others 1923 Bedford and Fleming 1928) both of which methods appear to be standing the test of time. The parietic curve however appears to have been relatively stable when other specific drugs have been given in the absence of induced pyrexia (Fordyce 1926 Halloran 1924 Hearn 1922 Yorke and Murgatroyd 1936 Stokes Miller and Beerman 1931).

The Table illustrates to some extent the different stages of the *übergangsbefund* referred to by Dattner (1933 1935)—namely successive return of first the cell count then the protein and finally the colloidal reactions to normal as the result of treatment. It will also be noted that slight reduction in the strength of the Wassermann reaction has been recorded in some cases.

CONCLUSION

The serological results in 22 cases of general paralysis treated with stovarsol by mouth warrant further trial of this method. The clinical results although favourable in some cases do not at present justify any conclusions.

Our thanks are due to Dr R. P. Septon (medical superintendent) and Dr J. D. Silverston (deputy medical superintendent) for their kind assistance and permission to submit this work for publication to Messrs May and Baker for providing the stovarsol; and to Mr G. Hannah who carried out valuable work during the investigations.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE

SECTION OF RADIOLOGY

At a meeting of this section held on April 16th the chair was taken by Dr DOUGLAS WEBSTER, the president and Dr HARRISON ORTON read a paper prepared by Dr COURTNEY GAGE on some of the less common lesions and special methods of

Investigation of the Alimentary Tract

and the influence of adjacent organs. Dr Gage had first considered sarcoma of the stomach which he believed could be distinguished from carcinoma when it was of the sessile type of myosarcoma growing into the lumen. The prognosis of this type was excellent. Myosarcomata might protrude into the lumen or burrow into the wall and distort the organ like an extrinsic growth. These growths like sarcoma as a whole might appear at any age between 8 and 80, being commonest about 40 though the peak for lymphosarcoma came earlier. They most often originated close to but not on the curvature and did not cause obstruction at either orifice. They were liable to degeneration and might become nodular from cyst formation. Pain might be prominent but cachexia and anæmia were less marked than in carcinoma. Bleeding was rare except from the myosarcoma projecting into the lumen. The radiologist was responsible for diagnosing these removable growths. Malignancy was low. The shape was that of a slightly squashed sphere or tangerine; the tumour might be pedunculated or sessile. Rupture through central necrosis produced a single deep

bleeding ulcer. Barium was trapped between the tumour and the gastric wall, causing a characteristic picture. Rugæ were pushed away on either side and smoothed out over the tumour. Smooth and regular if not ulcerated. Peristalsis would pass over a pedunculated tumour and go right up to a sessile one.

Retropentoneal hernias especially those into the duodeno jejunal fossa were Dr Gage's next subject. They were he thought more common than the literature indicated and were not always diagnosed as the cause of duodenal ileus. Lord Moynihan had described nine fossæ in this region but they could not be differentiated radiologically. Symptoms of obstruction varied from occasional colic to an acute emergency. Every case of duodenal ileus extending to the left of the midline should be regarded as of grave import and examined in detail. The intestine might appear as if wholly enclosed within a bag. Smaller ones might show only stasis in a knuckle of gut near the junction. Differentiation from diverticulum was easy: the barium shadow was not uniform and the gut line was continuous. Nor was the site a common one for diverticulum. Unusual causes of duodenal ileus included annular carcinoma of the third part of the duodenum and carcinoma just beyond the junction.

Crohn's disease had been described under various titles before its entity had been established by Crohn and his colleagues. The common site was the terminal ileum but the condition might occur elsewhere. Non-specific chronic inflammatory granuloma of the intestine was the best title. It was a multiple lesion usually found in young adult and in

males but recorded in both sexes and many ages. The part was increased in size, rather rigid and firm, presenting a sausage like tumour. Granulation tissue was found in all layers of the wall. The mucosa might ulcerate and perforate or be so swollen as to cause obstruction. The clinical picture varied with the site and the presence of acute, subacute, or chronic inflammation or obstruction. Acute cases suggested appendicitis. The string sign might be seen in radiological examinations of chronic cases. Examination of the small intestine required a special technique. Linear ulceration of the mucosa along the mesenteric border with tendency to perforate there was the most characteristic sign if it could be shown up radiologically as serrations. Adhesions were uncommon even with mesenteric abscess. The thickened gut might be freely angulated on the cecal wall or might even indent it, proving the freedom of the cæcum from involvement. *Ascaris lumbricoides* could be demonstrated by hourly radiograms, the opaque food filling the gut of the worm.

Dr S COCHRANE SHANKS pointed out that unusual methods were essentially experimental and difficult to assess. The true lateral view, with air as the medium and the patient blowing his nose, was a valuable technique for the pharynx. Oesophageal mucosæ might be difficult to demonstrate, but for varices a thick barium water cream was best. For the stomach a useful medium was a thick colloidal barium water cream, which mixed better with the juice and gave a better coating than tragacanth mixtures. Air inflation might give a good picture of polyposis and fundal tumours, but was contra-indicated in gastric ulcer from fear of perforation. For fundal tumours the gas bulb was sufficient. Spasm could be counteracted by benzamine sulphate. The pancreas was difficult to examine and a number of methods might be needed according to the lesion. Barium enemata might give evidence of steatorrhœa in chronic pancreatitis. Twining used the barium meal, taking lateral views of the supine patient to show the posterior incisura—a triangular filling defect—produced by the normal pancreas, and the influence of tumours on it. Gastric inflation might be used in pancreatic investigation to study the space between stomach and spine, but Twining's method was the better. Cases of acute obstruction should be radiographed lying supine in bed with the Schonander grid which showed fluid levels well.

The small intestine was generally well seen in the prone view, but sometimes Gage's technique was needed: a small barium water suspension meal was given (4 oz) and the patient kept prone throughout the five or six hours of the examination. This kept the distribution even. Radiograms were taken hourly in full inspiration. Another of Gage's methods was to fill the colon per anum and inject lipiodol through a urethral syringe to show up fistula. For gastro-colic fistula the enema method was better than the meal, as the flooding of the stomach with the enema was conclusive. Stierlin's sign was supposed to be due to a spasm of the cæcum but might be partly due to organic narrowing, the meal should therefore be followed by an enema, when the spasm might relax. The triple contrast method for study of the colonic mucosa must be preceded by complete evacuation for which the Sude chair was the best irrigation method. A colloidal preparation was the best. The thorium three stage enema was a variant. Thorium deposited better than barium in the colonic mucosa. As little of the medium as possible should be given and that intermittently. There were many

failures. No deposition or irregular deposition might result, or the bowel might fail to empty. Pittressin helped to produce emptying. The appearances of the first stage were those of the ordinary enema, except that the colon was less distended. After the vacuation the colon was plicated, showing haustration, and transverse and longitudinal plication. An irritable colon showed small plicæ, asterisk or honeycomb pattern appeared in polyposis or diverticulitis, and absence of plicæ in grave ulcerative colitis or neoplasm. After the air injection the calibre, contour, and anterior and posterior walls *en face* should be observed.

Dr R S PATERSON said that anatomical variations were most often due to failure to descend or to rotate. Faulty fixation might produce hypermobility. Intussusception was usually associated with a polyp or small growth in adults and was revealed by sudden arrest of the enema at the tumour, tailing off of the shadow into a fork, and sometimes a thin streak of barium through the intussusception. The barium enema in some cases cured the condition. Simple colitis in the acute stage might make the bowel too irritable to retain the enema, the lumen was much narrowed, and the line of barium might be no thicker than a lead pencil. Accurate pictures of the mucosa, if obtainable, gave a characteristic tufted pattern. In more chronic forms the spasticity and irritability became reduced and the colon appeared as a parallel walled tube with no haustra. Often the enema flowed unusually quickly. Notching had been described as representing ulcer craters, but was an unusual finding. The diagnosis of colitis was really clinical. Polyps might occur anywhere, and vary from a large single one, causing filling defect, to a condition of polyposis which gave a characteristic marbled shadow effect beautifully shown by the double contrast method. Certain foods gave an identical appearance, and retention of fæces also caused diagnostic errors, preparation for the enema should therefore be very thorough. In conclusion, Dr Paterson showed radiograms of a case where a barium enema very satisfactorily converted a breech presentation into a vertex.

Dr G B BUSH spoke of displacements due to extrinsic causes below the diaphragm. Routine investigation would sometimes reveal unsuspected enlargements under the costal margin, in the pelvis, men obese patients. The examiner must appreciate laboratory normal variations and must know the brief indications of the peritoneum and the abdominal masses. Enlargements of the spleen cause the stomach and cause an indentation.

Stovarsol, new growth of the greater curvature, pushed the splenic flexure down. Renal tumours had variable effects on the stomach, a large growth might push the stomach down and to the left and indent the lesser curvature, and also displace the descending colon forwards and inwards, without affecting the flexure. Retroperitoneal neoplasms displaced the stomach. Enlargements of the head of the pancreas—cysts or growth—played out the curve of the duodenum. Enlargements of the liver depressed the duodenum and were unmistakable. The gall bladder was occasionally displaced by a liver cyst. Many tumours affected the transverse colon and flexures. Pelvic swellings gave interesting displacements of the mobile sigmoid, but reduction in its mobility must be demonstrated to verify true displacement. Pregnancy had little effect on the sigmoid because the uterus at first enlarged at right angles to the plane on which the colon was visualised.

ovarian cysts pushed the sigmoid up and uncured the S bend. An enormous lipoma originating under the diaphragm had displaced the stomach and colon right over to the right side.

LIVERPOOL MEDICAL INSTITUTION

At a meeting of this society on March 18th with Prof R E KELLY the president in the chair a paper on

Lobectomy

was read by Mr HUGH REID. He outlined the common indications and complications of lobectomy and illustrated the technique by means of a colour film. Only recently he said had the mortality of this operation been so lowered as to bring it within the region of practical surgery. Brunn had described the one-stage operation in 1920 and although various refinements had been added his fundamental principles had not been altered and this was the method adopted by Mr Reid himself. He pointed out, however, that the one-stage operation had not been accepted by everyone for every case of lobectomy. Alexander for instance had made out a very good case for the two-stage method, particularly as regards complications. The greatest field for Brunn's operation was in bronchiectasis and in carcinoma of the lung. It had been shown that if the whole lung was removed from one side the empty cavity filled up with a reticulated fibrin while the remaining lung increased in size by hyperplasia and hypertrophy without emphysema the mediastinum being pushed over the ribs on the affected side falling in and the diaphragm rising in an attempt to obliterate the cavity. If only one lobe was removed it was surprising to notice that after a few days the remaining part of the lung had enlarged to obliterate the cavity completely.

Dr N B CARON spoke of the great benefit that a patient of his had received from the operation described and referred to other cases in which still more extensive lobectomy had been successfully performed. The cases required careful diagnosis and selection with full investigation of the supposedly anaesthetic or obese in order to avoid disappointments. As the course of medical treatment with possible anaesthesia should be given a thorough trial before a lobectomy was undertaken. The ideal was of course a mild diaphragmatic chest when ever possible and more resembling a child to be made to attain this.

Dr ROY also agreed that to advise lobectomy was a serious responsibility. The physician in charge of a patient with bronchiectasis was in a difficulty. On the one hand the operation was a severe one with a high risk—though with the development of their technique surgeons skilled in lung surgery were now achieving far better results especially in the young. On the other hand the natural history of the disease made it certain that many a patient with bronchiectasis though reasonably well at the moment would in perhaps five or ten years time be a distress to himself and to those about him. To wait until the patient and his friends were desperate before advising operation was fair to neither patient nor surgeon. By that time an originally unilateral bronchiectasis might have become bilateral, with widespread damage to the lungs and in any case the patient would be a poor subject for surgery. If operation was to offer any chance of cure it was the duty of someone with expert knowledge of the disease to advise it after full careful and unbiassed consideration at a time when the

patient was fit enough to have a good chance of recovery from an extremely severe procedure. That is the very time however when there was a temptation to carry on with merely palliative treatment for while the doctor knew the course and future of the disease the patient and his friends could hardly grasp it. With the modern advance in lung surgery the physician could feel reasonably happy in passing on young and otherwise healthy subjects to the competent thoracic surgeon. With older patients there was still need for the utmost caution in weighing up the pros and cons of surgical treatment with a bias at present against it. In spite of occasional recorded cases of lobectomy or total pneumonectomy for bronchial carcinoma, both physicians and surgeons would agree from actual experience that the number of cases suitable for this procedure must be very few indeed.

Mr H V FORSTER said that Frenchner of Stockholm had described a close fitting bronchial catheter and an ingenious instrument called the spiropulsator which could be used for positive pressure narcosis to one lung alone. These instruments might be useful in the operation of lobectomy or pneumonectomy. The laryngologist had been a pioneer in the study of lung disease by bronchoscopy but now he saw how these aids were being employed by the physician or surgeon himself. Possibly the bronchoscopist by helping to avoid pulmonary atelectasis in children would be able to contribute to the prevention of established bronchiectasis.

The Value of a Bronchoscopic Clinic

Mr J E G MCGIBBON and Dr E T BAKER DATES contributed a joint paper in which they described the difficulties of accurate diagnosis in certain cases of pulmonary disease even after the most careful clinical examination and investigation. If bronchoscopy was properly carried out under local anaesthesia it was a safe and harmless procedure even in the presence of serious lung disease. They then reviewed the work and methods of the bronchoscopic clinic of the Royal Southern Hospital Liverpool. The number of foreign body cases was small. Suspected bronchial neoplasm pulmonary suppuration such as bronchiectasis and lung abscess dyspnoea due to tracheal and bronchial obstruction collapse of the lung recurrent haemoptysis of obscure origin and certain doubtful cases of asthma, all called for bronchoscopic inspection and appropriate treatment when possible and formed the bulk of the work of the clinic. Foreign bodies were classified as radiologically opaque and radiologically non opaque and with regard to their composition as organic and inorganic. The organic foreign body cases were dramatic and serious and called for immediate removal. Several cases of non-opaque organic foreign bodies were encountered which had previously been thought to be lung abscess unresolved pneumonia and new growth. Bronchoscopy revealed an unsuspected foreign body removal of which brought about resolution of the lung condition and cessation of symptoms in the majority of cases. Careful investigation whenever possible by direct radiography and with Lipiodol was essential in the cases under haste in attempts at unskilled removal proved as great a source of danger as the foreign body itself. Pulmonary suppuration in the widest sense was next discussed; it was necessary to bronchoscope all cases of unresolved pneumonia localized non tuberculous pulmonary fibrosis lung abscess and bronchiectasis, in order to exclude suppuration and pneumonitis distal to simple and malignant bronchial

neoplasms and foreign bodies True unresolved pneumonia and localised non tuberculous pulmonary fibrosis were rare in their experience and, in most cases referred to the clinic with this diagnosis, a cause such as foreign body or new growth had been found The diagnosis should only be accepted with caution after a process of exclusion, especially in the adult The results of bronchoscopic aspiration and lavage in chronic lung abscess and bronchiectasis were in their experience disappointing and no better than that obtained by postural drainage when properly carried out Simple new growths were rare, all cases discovered during life had been revealed by bronchoscopy and what had been thought to be an extremely rare condition might prove to be much commoner when bronchoscopy is more generally employed in obscure lung lesions The majority of these growths were curable by endoscopic methods—simple removal, diathermy, and radiation—but if left untreated they ultimately gave rise to serious secondary effects Angiomata and fibromata had been seen and treated successfully at the clinic Malignant bronchial new growths were common, by bronchoscopy their diagnosis could be made beyond doubt In cases with suppuration distal to a bronchial occlusion by growth, the process of dilatation with bougies of a carcinomatous stricture, removal of exuberant portions of growth by biting forceps, and the introduction of radon seeds or a radon tube lead in certain cases to re aeration of the collapsed portion of lung and drainage of secretions By such means the complicating suppurative lesion was usually relieved, the toxæmia lessened, and the sufferings of the patient were minimised Cure, of course, was impossible at this stage, and probably would remain so in view of the situation of the growth and its mode of spread into the lung parenchyma and mediastinum In early cases of bronchial carcinoma the clinical and radiological findings were negative, and the patients looked well, recurrent hæmoptysis was the only presenting symptom If any successful treatment were possible for this terrible condition, its success would depend on early diagnosis, and for this bronchoscopy was essential A case suitable for lobectomy had not yet been seen In some cases the diagnosis of malignant disease had been disproved by bronchoscopy and foreign bodies removed Except in cases of emergency, bronchoscopic examination should always be preceded by complete clinical and radiological examination including lipiodol bronchography The cases should be followed up, when the significance of unusual findings could be assessed, as it was not always possible to remove suitable fragments for pathological examination Bronchoscopy would always remain team work, and it necessitated the closest liaison between laryngologist, physician, and radiologist in a well equipped clinic to which cases would be sent from a wide area

Mr FORSTER said he would like to understand better the value of the diathermy cautery as used in a bronchus when compared with the insertion of radon seeds in cases where the obstructing growth had not been proved to be malignant Some cases after operations on the upper abdomen by the general surgeon used to develop other pneumonia, at least in his early student days The inhibition of diaphragmatic respiration had something to do with this The laryngologist rarely saw such complications in spite of the greater danger in his operations of inhalation of blood and secretions He had not met a case of lung abscess after these operations in the practice of his teachers and so far had been

spared the complication in his own Further, he had found the asthmatic patient stood either marvellously well though he had seen an asthmatic paroxysm under nitrous oxide

Mr COURTENAY YORKE said that in his opinion the principal use of the bronchoscope would always be the removal of foreign bodies, of which very many are not opaque to X rays and quite unsuspected He felt dubious as to the value of radon seeds in the treatment of bronchial carcinoma The inaccessibility of the lower edge of the growth and the limitations of radon seeds both in range and duration of action made him feel that on the whole the possible temporary relief would hardly outweigh the risk and discomfort involved in their insertion Malignant disease in the larynx was a hundred times commoner in men than in women, and he thought, on that account, an inquiry into the relative sex incidence in bronchial carcinoma would be very interesting and might raise important questions in regard to ætiology

Dr V COTTON CORNWALL said that in investigating the cause of hæmoptysis, bronchoscopy was sometimes the only means by which a correct diagnosis could be made He quoted a case at Fazakerley Sanatorium where all investigations, including bronchography, had been negative and bronchoscopy had revealed a bronchial carcinoma

MANCHESTER MEDICAL SOCIETY

At a meeting of this society held on April 7th, with Mr GARNETT WRIGHT, the president, in the chair, Dr S W PATTERSON spoke on

Neoplasm of the Colon

In presenting the results of an investigation of 82 cases of carcinoma of the colon and rectum he said that Sir Edmund Spriggs had during the last few years analysed the admissions to Ruthin Castle of patients with diseases of the colon and had collated and published papers on diverticulitis, ulcerative colitis, and functional disorders of the colon Amongst the 82 cases of cancer of the colon and rectum in the series 68 were in the various parts of the colon and 14 in the rectum Two thirds of the cases had occurred in men The average age was 62 years, 64 for men and 57 for women The age of most lay between 50 and 70, five were under 50 years old and eight were over 70 The sigmoid and pelvic colon were the parts of the colon most affected The length of history ranged from a week or two to three years, but was usually a few months The lesion was sometimes well advanced before it caused any sign or symptom

The symptoms at onset were divided into five main forms (1) increasing constipation, (2) irregular stools or looseness, colitic type, (3) pain, usually above or below the navel, but occasionally in the back thighs, or rectum, (4) upper abdominal discomfort or nausea, sometimes related to food-dyspeptic onset, (5) the early passage of blood from the rectum There might be an overlapping of two types of onset in the same patient In some cases the onset was insidious and the bowel symptoms were almost negligible until some other condition led to the investigation of the digestive tract, as in a patient with recurring lumbago which was found to be due to a secondary growth in the bodies of the eleventh and twelfth thoracic vertebrae, originating in a carcinoma of the descending colon Of the 14 cases of carcinoma of the rectum the age at the onset of symptoms varied from 37 to 75 years. The took the form of a frequent desire to stool or diarrhoea

in 11 constipation in 2 and epigastric pain increased after meals in 1. Two only had noticed no blood in the motion. 5 had suffered serious loss of weight and in 1 man pain with micturition was an early and troublesome complaint. In the diagnosis the triad of constipation more or less associated with diarrhoea and hemorrhage was characteristic but only half of the patients with cancer of the colon complained of serious constipation and constipation might occur in ordinary intestinal stasis. Bleeding from the bowel occurred in 80 per cent. of the patients and was not seldom ascribed to piles.

Amongst the general symptoms loss of weight and anaemia were predominant. The anaemia might be severe in cases of carcinoma affecting the proximal colon without much obvious blood occurring in the motion whereas in cases affecting the distal colon where blood and mucus were common anaemia was not a prominent symptom. In all cases rectal and sigmoidoscopic examination should be carried out. The patients might thus complain of dyspepsia or general malaise usually with colitic symptoms: constipation diarrhoea pain stoppage or hemorrhage, but always a change in the character of the motions. Dr Patterson illustrated the radiological diagnosis by a series of X ray photographs and diagrams. In differential diagnosis the age factor was one which had to be considered.

In regard to treatment full discussions from the surgical point of view had been published in the weekly medical journals during the last few years by Sir David Wilkie H. B. Devine H. H. Rayner and E. K. Martin. In the present series excision was carried out in 13 of the cases of carcinoma of the colon and 2 of carcinoma of the rectum. Colostomy was done in 15 and 10 cases respectively while a short circuit without removal was possible in 9 of the colon cases. A consideration of the length of history with the results of surgical treatment showed that if advice had been sought earlier and a diagnosis made many more lives could have been saved.

In the subsequent discussion Dr R. W. LUTTON, Prof. MORLEY Mr. RAYNER and the PRESIDENT again stressed the importance of early diagnosis and attention to the commencing disturbances of the bowel.

REVIEWS AND NOTICES OF BOOKS

Practitioners' Library of Medicine and Surgery

Vol. XI *Eye Ear Nose and Throat* Supervising Editor GEORGE BLUMER M.A. M.D. David P. Smith Clinical Professor of Medicine Yale University London; D. Appleton Century Co. 1937. Pp. 1153. 50s. (in sets only).

This imposing volume has been compiled by over forty American specialists many of whom are well known and respected in this country. It possesses the merits and the defects of most of such compilations. On the one hand there are chapters by distinguished authorities on subjects they have made especially their own and on the other there is overlapping and unevenness with not a few omissions. Thus no mention is to be found of inflation of the ear by the method of Politzer nor through the Eustachian catheter in the treatment of recent catarrhal deafness and the technique of the introduction of the catheter is nowhere described. Indeed in the discussion of acute catarrhal otitis media Creighton Barker visualises an inflammation accompanied by fever pain and usually perforation of the drum rather than the common cold in the ear associated with deafness and fullness for which inflation is valuable. An instance of overlapping is the description by R. E. Buckley of cancer of the larynx followed by a chapter on the same subject by Louis Clark. In the latter only the operation of laryngoscopy is described while Buckley says that the results of radium therapy have been so poor that its further use in the treatment of cancer of the larynx should be absolutely discouraged. The brilliant results obtained in England by the introduction of radium according to the fenestration method of W. D. Harmer and A. G. Finkel might with advantage be more widely known and practised in the United States.

A. Kopetzky has contributed a beautifully clear and helpful exposition of the application of physiology and pathology to the study of suppurative lesions of the middle ear which together with the preceding chapter by D. M. Jerlo and J. J. Lotter forms an admirable basis for the understanding of inflammatory processes in this region. Acute suppuration of the ear is discussed in four separate chapters;

the importance of the subject may be sufficient excuse for the lengthy treatment but the mass of reading is uninviting and curtailment should have been possible. The section on diseases of the eye is very complete. The scope of the book is not intended to include descriptions of those operative procedures for which the equipment of a specialist is required; nevertheless those employed in the treatment of cataract and glaucoma are fully discussed and illustrated as also is the operation of lateral pharyngotomy for cancer of the laryngopharynx. The work is not a text book but rather a collection of excellent essays on these special subjects which well deserves a place in the practitioner's library.

Electricity in Therapeutics

By HAROLD H. U. CROSS Ph.D. formerly Research Worker at the Stanford University California; Certificate Electro Radiology Faculty of Medicine Paris. With a Preface by Dr G. LORON BOURGIGNON. London Crosby Lockwood and Son 1936. Pp. 378. 25s.

This book does not deal entirely with electrical treatment. There is a chapter entitled The Elements of Electro diagnosis and a considerable portion of it is devoted to the chronaxie and its determination. A short chapter has been written on ultra violet ray treatment and there is a brief résumé of infrared ray therapy. This book has been written to supply such technical information as will show the student and practitioner the underlying electrical and chemical principles of electricity in therapeutics. It includes much more however than technical information. Methods of subjecting patients to the different physical agents and various ways of treating disease by their means are also described. Dr Cross refrains from expressing his own views on the selection or prescription of treatment but he describes a few of the cases which he has treated. Considerable attention is given to the galvanic current and its therapeutic uses. The chapter entitled transcranial ionization will be of especial interest to British readers. This form of treatment was introduced by Bourguignon. It is recommended for long-standing cases of hemiplegia with con-

tracture For cases of facial paralysis, especially those with contracture, indeed, it is said to be a "sovereign remedy" The section of the book devoted to high frequency currents is much smaller than that concerned with the galvanic current and its uses Generators, electrodes, and accessory apparatus are fully described, but only ten pages are allotted to the medical and surgical applications of high frequency currents The work conducted in this country on the diathermic treatment of the pelvic organs does not appear to be mentioned, although there is a description of Sloan's method of treating cervicitis and vaginitis by ionisation The author also describes the use of ultra violet rays and quartz applicators in the treatment of urethritis, erosion, vaginitis, cervical catarrh, leucorrhœa, and gonorrhœa

One form of treatment said to be used with benefit in inflammatory conditions is not regularly practised in this country High frequency currents derived from a high voltage source are applied by way of glass or quartz electrodes of various shapes and sizes to the skin or introduced into such channels as the nose, rectum, or vagina The current is said to exercise a "revulsive" action The risk of breakage of the electrode *in situ* is mentioned Should this happen the operator is instructed to keep the patient calm and flood the canal with warm olive oil, to remove pieces with forceps and reassemble as nearly as possible to ascertain that all has been recovered

There are three appendices One is a selected bibliography, another contains a number of diagrams showing the motor points of muscles and nerves with descriptions of the action of the muscles, and the third gives advice on the resuscitation of those who have apparently been electrocuted

Kidney Pain

By J LEON JONA, D.Sc., M.D., F.R.A.C.S., M.C.O.G., Hon. Assistant Gynaecological Surgeon, Women's Hospital, Melbourne London J and A Churchill, 1937 Pp 95 7s 6d

RENAL pain of unknown origin is very commonly met with in practice, more especially among female patients It is therefore a subject of great practical importance, and the object of this little book is to bring before practitioners certain views on the causation of obscure renal pain and on its treatment Dr Jona has been working for the last ten years on the physiology and pathology of the renal pelvis, but unfortunately the outcome of his researches are still too theoretical to be of much use to the busy practitioner It is obvious, however, that he has read very widely on the subject and the extensive bibliography supplied will be of the utmost use to those concerned with this region A better title for the book might have been "Introduction to the Study of Renal Pain," for it will certainly provide an admirable survey from which further fruitful work may spring

Enzyme Chemistry

By HENRY TAUBER Ph.D., Consulting Chemist, New York Medical College and Flower Hospital London Chapman and Hall 1937 Pp 243 15s

THIS book will find a warm welcome in the libraries of chemists, biochemists and physiologists who require an up to date summary of our knowledge of the chemistry of enzymes and their mode of action Dr Tauber deals mainly with the actual chemical and physical nature of the enzymes rather than with their complicated action, and a book written on this aspect

of the problems presented has been badly needed for years There are many works on such subjects as the kinetics of enzyme reaction, and mathematical treatises on the many relationships of enzyme to substrate, but the worker who wants to find out anything about the actual chemical nature of the ferments themselves is faced with the need to make an arduous search through the literature

Even the most erudite among general biochemists will get some surprises when reading through the book For instance, it may well come as news to them that crystalline trypsin and pepsin have been prepared, and that ferments such as carboxy polypeptidases have been crystallised Dr Tauber has undoubtedly provided a most useful addition to the library of any worker whose interests are directly or indirectly concerned with enzymes

Complement or Alexin

By T W B OSBORN, University of Witwatersrand, London Humphrey Milford, Oxford University Press 1937 Pp 116 7s 6d

Dr Osborn has done a useful service in bringing together the available knowledge on the subject of complement in the form of a brief and well arranged monograph The work takes no new standpoint nor does it bring forward any new facts of importance but it is obviously written with real understanding of the subject, and if little criticism appears in the pages, a good deal, we imagine, has been expended on the omissions As Prof R A. Peters says in his introductory note, complement is a "mysterious and interesting" reagent It is also a very important reagent in practical laboratory work, and all who have to do Wassermann's or other fixation test will profit by reading this excellent account of its properties

1936 Year Book of Dermatology and Syphilology

Edited by FRED M WISE, M.D., Professor of Clinical Dermatology and Syphilology, New York Postgraduate Medical School and Hospital of Columbia University, and MARION B SOLZBERGER, M.D., Associate Professor of Dermatology and Syphilology at the School Chicago Year Book Publishers, London H K Lewis and Co. 1936 Pp 720 12s 6d

THE editors of this valuable publication, since its inception as one of 10 similar year books (including dentistry) in 1931, have adhered to the same programme and classification This volume has been enriched by abstracts from discussions and papers read at the ninth international congress of dermatology and syphilis held at Budapest in September 1935, an event which must have made still harder the selective duties of the editors As in former years they have themselves contributed an introductory essay on a subject of common therapeutic interest Last year they chose eczema in this issue they present a detailed survey of the treatment of urticaria in its acute and chronic manifestations, and any reader who has exhausted his armamentarium in an obstinate case of that disease may hopefully seek here some new measures for its alleviation or cure Among the more important extracts are those from papers dealing with the control and cure of syphilis, including two which present the results of treatment by Nepharsen—the new triarseneol for which reduced toxicity is claimed A special feature has been made of the recent studies and advances in the pathology of the virus disease

and those associated with disorders of the hæmopoietic and reticulo-endothelial systems

The table of contents is divided into 14 sections under which the editors have abstracted papers dealing with mycotic infections eczema allergy and immunology drug eruptions hamatogenous dermatoses miscellaneous dermatoses cancer leukaemia and allied conditions chronic granulomas other than syphilis non-syphilitic venereal diseases dermatological therapy physical therapy experimental studies and finally syphilis in all its various aspects. As an addendum to some of the more important communications and where they do not altogether agree with the conclusions of the authors quoted the editors have submitted criticisms or alternative views which will be found of considerable interest and occasional assistance. Dermatologists owe a big debt to the industry of those who have helped to collect and collate the best of the new work on diseases of the skin and have provided such a comprehensive and reliable annual.

1936 Year Book of Obstetrics and Gynecology

Obstetrics Edited by JOSEPH B. DELEE, A.M. M.D. Professor of Obstetrics University of Chicago Medical School. *Gynecology* Edited by J. P. GREENHILL, B.S. J.D. F.A.C.S. Professor of Gynecology Loyola University Medical School Chicago. Year Book Publishers London H. K. Lewis and Co. 1937 Pp 704 10s 6d

The appearance of the 1936 number of this year book reminds one of the continued and widespread activities of Prof. DeLee who edits the obstetric section of this book. His editorial remarks are characteristically trenchant and add to the general interest of his summaries of new work. Prof. J. P. Greenhill is responsible for the gynecological section which is no less well compiled. The volume is of handy size and provides an admirable review of the best of the year's work in this specialty chosen liberally from all parts of the world.

Health of the Mind

By J. R. REES, M.D. Director of the Institute of Medical Psychology London. Faber and Faber 1936 Pp 230 6s

Dr. Rees has brought his book up to date by the inclusion of a number of minor points in various chapters. The volume is designed to appeal not to the expert but to the intelligent layman, the school master and the spiritual guide. Technicalities are cleverly avoided and the skill of the exposition added here and there by diagram makes many a theoretical tangle seem simple. The chapter on childhood is a sound display of common sense. For those who tremble on the brink of suggesting psychological treatment for themselves or their friends this volume will be a disarming invitation. Since it is the Institute directed by Dr. Rees has reverted to its former honoured name and in future will again be known as the Tavistock Clinic.

Reactions of the Human Machine

By JOHN LERNBERT DENT London: Victor Gollancz 1936 Pp 288 8s 6d

This volume is frankly materialistic biology and from the very beginning determinism is the premise of the argument. Movement or reaction is a special quality in living things and having admitted this special quality it is not difficult to

build up a consistent dynamic structure of the organism of man in its individual and social reactions. The argument in fact is so very consistent that many apparently strange explanations fall into their place in the general scheme of the book. In many ways the author's thesis is an extension of the theories of Pavlov. It is with these theories in view that the book should be studied. Those readers who look for consistency and fidelity to biology in the study of mental medicine will find much stimulation in its contents. Neurologists in particular will look with favour upon it. Some few psychopathologists may be either irritated or scornful.

What Science Stands For

By Sir JOHN BOYD ORR, F.R.S. Prof. A. V. HILL, Sec. R.S. Prof. J. C. PHILLIP, OBE, F.R.S. Sir RICHARD GREGORY, Bt. F.R.S. Sir A. DANIEL HALL, K.C.B. F.R.S. and Prof. J. HOOVER, F.R.S. London: George Allen and Unwin. 1937 Pp 172 5s

SCIENCE represents the satisfaction of man's curiosity and in common life it stands on the one hand for the addition of many facilities and conveniences to his material existence and on the other for much of his intellectual and spiritual refreshment and inspiration. The first consideration appeals more to those who do not know by personal experience what science is the second to the initiates. Both points of view are represented to various degrees in the six essays of this symposium. All of them are well worth reading and most of them are sufficiently provocative; the happiest expression of what seems to be the real truth comes from the editor of *Nature*.

An Introduction to Medical Science

By WILLIAM BOYD, M.D. FRCP Professor of Pathology in the University of Manitoba London: Henry Kimpton. 1937 Pp 307 16s

Prof. Boyd has written three good books on pathology and he now adds a baby to the family. Despite its title it is an elementary text book of pathology intended for junior students, nurses, technicians and perhaps the lay public. It is not more attractive than the average infant and while it is certainly not bad it cannot unreservedly be called good. In places the writing is careless—e.g. in the account of rickets. It may well be of use in its special field until someone succeeds in the extremely difficult task of composing a better semi-popular guide without tears.

1 A Doctor at Work and Play

By SIDNEY H. SNELL, M.D. B.S. Lond. D.P.H. London: John Bale, Sons and Curlew. 1937 Pp 331 12s 6d

2 Scalpel and Sword

By Sir JAMES ELLIOTT, M.D. Sydney Angus and Robertson. 1936 Pp 215 7s 6d

1. It is the first of these books that the late Dr. Snell shows himself to have been possessed of the vigour and simplicity characteristic of the Victorian professional class. A Westcountryman who received his professional education at University College Hospital he contrived to combine a busy professional life with numerous outside interests and activities. Frequent travel, golf, sailing, big game farming and fox hunting were some of the things he found time for and in common with other horse-lovers and modern educationists he found that a spirit of

animal will sometimes go better in a snaffle than on a curb. The book, illustrated with photographs and abounding in anecdotes, is the straightforward and colloquial chronicle of a life remarkable perhaps for the quality and variety, rather than the rarity of the experiences packed into it. The reader is left with an impression of the author as an attractive person, full of energy, kindness, and the joy of living.

2 Sir James Ellhott writes with considerable literary skill and his adventures are set against a very different background. Educated at Edinburgh and perhaps a shade condescending towards the older universities he is delightfully reminiscent about his former teachers. As a doctor he saw service with a field hospital in the South African War and, during the late war, was senior medical officer on the ill-fated *Mahono*. Much of the book is concerned with an interesting account of the manners and customs of the Maoris and the author's gift for happy phrase is well exemplified in the chapter on America.

Snow on Cholera

Being a Reprint of Two Papers by John Snow, M.D. Together with a Biographical Memoir by B. W. RICHARDSON, M.D., and an Introduction by WADE HAMPTON FROST, M.D., Professor of Epidemiology, Johns Hopkins School of Hygiene and Public Health, New York. The Commonwealth Fund, London. Humphrey Milford, Oxford University Press 1936. Pp 191. 10s. 6d.

This reprint of Snow's classical papers on cholera has been published under the auspices of the Commonwealth Fund (New York) by "Delta Omega," an American society of public health, to whose interest we already owe a reprint of William Budd's *Typhoid Fever*. In addition to the second edition of Snow on the Mode of Communication of Cholera it contains his interesting paper on Continuous Molar Changes, an oration given to the Medical Society of London on its eightieth anniversary. The edition also includes the memoir on Snow's life by his friend Sir Benjamin Richardson which was originally published in the *Asclepiad* in 1887, and which is everything that a brief biography should be. A short introduction by Prof. Frost gives an informative and just account of Snow's place in the history of epidemiology. The apparatus is completed by a bibliography of Snow's works and a frontispiece portrait of Snow. The book is attractively got up. It includes the coloured maps of the original second edition (1854), typographically it is as near as possible a reproduction of the original and the binding and lettering are also reproduced. To the discriminating reader these details will add much to the enjoyment of owning and reading the book, which has obviously been published as a labour of love and is being sold at what must be below cost price. We can hardly think of a better gift for any young doctor interested in public health work than this edition of one of the most interesting and inspiring of the classics of hygiene.

Diseases of the Respiratory Tract

Eighth Annual Graduate Fortnight of the New York Academy of Medicine. London. W. B. Saunders Co. 1936. Pp 418. 24s.

THIS is a collection of lectures to post graduate students and practitioners by twenty one authorities on special aspects of respiratory disease. Such a collection could not be comprehensive and the lecturers have wisely chosen subjects rich in specu-

lative and controversial matter. The general standard of the various papers is high and reference must be made to one or two of particular interest. A lecture by A. R. Dochez on the common cold gives the recent evidence for the conclusion that the causative organism is a filter passing virus, in the writer's experience even after prolonged immunisation there is no diminution in the number of colds experienced, although there may be some decrease in severity.

Other papers of particular merit are those on bronchoscopy by Chevalier Jackson, and on bronchiectasis by J. B. Amberson. Recent views on the pathology of pulmonary tuberculosis are expressed in two papers, the first by J. A. Miller on the evolution of pulmonary tuberculosis, and the second by A. R. Rich on immunity in tuberculosis, the latter insists strongly on the absence of any real basis for the view that hypersensitivity (allergy) is necessary for development of immunity. In a paper on carcinoma of the lung Lloyd E. Craver discusses the brilliant results which have recently attended lobectomy and pneumonectomy in certain cases of this disease, but he is careful to call attention to the very small proportion of cases which are suitable for this form of treatment. In many cases the growth is inoperable when first discovered, either on account of its anatomical position or because of the early appearance of metastases. Of the remainder a considerable number are not fit subjects for major surgery either on account of age or general weakness. In Craver's experience internal or external irradiation is here mostly the treatment of necessity rather than of choice, although palliation of symptoms often occurs he is doubtful if life is prolonged by these measures.

NEW INVENTIONS

A NEW TYPE OF NEEDLE HOLDER

I DEvised this needle holder primarily for use in cleft palate operations in children, but it is equally useful in all operations, in any situation where space is limited and accurate suturing is essential. The majority of needle holders were too massive and cumbersome for the small needles employed. Apart

from this, when working in such a confined space one's hand invariably tended to obscure the view of the operation field. Owing to the pronounced "cast off" in the handles, the needle is always in view, and the slight curve in the jaws and the fineness of their points enable even the smallest sizes—e.g. Lane's—to be held securely in various positions. The sutures can thus be inserted from any angle which is impossible with the ordinary types of needle holders.

The needle holder has been made for me by Messrs. Down Bros., London, S.E.

G. L. PRESTON, F.R.C.S. Edin.
Honorary Surgeon to the Prince of Wales's
Hospital, Plymouth

THE LANCET

LONDON SATURDAY APRIL 24 1937

A MASTER OF EPIDEMIOLOGY

THE classics of epidemiology wear better perhaps than those of any other branch of medicine. The student of epidemic disease may still find immediate help and inspiration in the writings of FARR and BUDD MURCHISON and GRAVES, BRETONNEAU and TROUSSEAU or HIRSCH and CREIGHTON and the more his experience grows does he find them instructive. This is not because epidemiology is an unprogressive science, its advance has been as spectacular as that of any speciality. That good observation in the field of epidemic disease is not readily superseded depends partly on the fact that many epidemic diseases were more common and more easy to study in bulk in the past than now but partly also on the circumstance that it was the disease rather than the patient that was studied and the *argumenta ad hominem* which tend to make the doctor a good friend but a bad scientist were largely eliminated.

JOHN SNOW has hardly yet been accorded a place in the front rank of the masters of epidemiology but his famous treatise on cholera is a cameo of medical writing and a model of epidemiological inquiry. We welcome the cheap and elegant reprint of the work reviewed on another page which has been produced through the good offices of the Commonwealth Fund and makes available a story as interesting and instructive as any in medicine. Cholera as a serious epidemic disease had a brief and meteoric career in England. It reached the country somewhere about 1830 and in 1854 it fell on London like a wolf on the fold. Had it arrived half a century earlier it might have caused a major national disaster as it was the fold was being watched over by such alert shopkeepers as WILLIAM FARR, WILLIAM BUDD and JOHN SNOW. Within half a dozen years it was attacked and practically exterminated in this country and foremost in the event was JOHN SNOW. SNOW had studied cholera in Newcastle some ten years earlier he knew his enemy and he achieved its destruction in an astonishingly short time. Within a few weeks from the outbreak he was able to put on permanent and unmistakable record his thesis that cholera was a water borne disease, that the source of infection was the dejecta of cholera patients and that the *matrices morbi* was what we should now call a germ. SNOW was a fine example of the naturalist doctor characteristic of English medicine. He was in the best sense in the Hunterian tradition. A physician with a busy practice he yet could find time for intense observation and for scientific work of the highest quality. It is sometimes said that this is impossible under present-day conditions and research workers demand whole time facilities. It remains certain that such men as HUNTER or SNOW would have

succeeded in finding opportunity for their work in the face of practically any difficulties though admittedly these men lived dedicated lives and their successes were not won without material and social sacrifices.

SNOW was one of the pioneers of anaesthetics and he must have taken a large part in popularising the use of anaesthetics at childbirth for it was he who gave Queen VICTORIA her first anaesthetic and thus set the fashion. He does not seem to have benefited financially to any extent from this practice though all the fine ladies of the time must have demanded the Queen's anaesthetist and would surely have been willing to pay substantially for his services. We are told by his friend RICHARDSON however that his income never exceeded £1000 a year and this explains much. SNOW wrote some fifty papers on medical subjects many of them on anaesthetics but his masterpiece is the little treatise of some 140 pages in which he records his investigations of the London out-breaks of cholera of 1849-54. The story reaches its highest pitch of interest in the account of the epidemic perhaps the most severe in English experience which in 1854 caused over 500 deaths in ten days in the very heart of the West End—in the neighbourhood which now backs on the Regent Palace Hotel. The story is known to every student of epidemics—how SNOW gratuitously took upon himself the task of investigation how by ingenious and unremitting inquiry he traced case after case to the Broad-street Pump how the widow of a percussion cap maker retired in Hampstead sent a messenger daily for a bottle of water from the Pump as she preferred it to the local waters how she died, a unique case in her salubrious neighbourhood how her niece who visited her drank some of the treasured water, returned to her residence in a high and healthy part of Islington was attacked by cholera and died also how the men of Mr Huggins a Brewery hard by the Pump knew of a better pump and all escaped—such are some of the elements which makes SNOW's report of perennial scientific and human interest. The story has been retold by Dr H. H. SCOTT in his excellent book, *Some Notable Epidemics* but this should only whet our appetites for the original sources. The appearance of a cheap reprint of SNOW's classic will it is hoped gain many new admirers for this representative as RICHARDSON calls him of medical science and art of the Victorian era.

CIRCULATORY COLLAPSE

IN a recent issue when discussing the effect of extensive local injury we surveyed various theories of the cause of secondary shock. These theories assumed a loss of fluid with diminution in the volume of circulating blood and differed chiefly in their explanation of how this loss was brought about. It is generally taken for granted that a total blood volume which is small in relation to the capacity of the vascular system is sufficient to start the vicious circle seen in surgical shock but this disproportion between volume and capacity may

well be an accompaniment rather than a cause of the condition. Surgical shock may, for instance, be due to some profound dislocation of function in the central nervous system, of which vasomotor incoordination is merely one of the more serious manifestations. S. WEISS, R. W. WILKINS, and F. W. HAYNES of Boston² have done work of great interest in this connexion. By using sodium nitrite they are able to produce a state of circulatory collapse in which the condition of the subject closely resembles that seen in shock, but the state is reversible in a matter of seconds. The subject is placed in a horizontal position and given a dose of nitrite which has little or no effect so long as he remains lying down. After a few minutes he is raised into a vertical, or nearly vertical, position, with dramatic results. Yawning more and more often, he develops sighing respiration, restlessness, increased peristalsis, and warm and then cold perspiration in rapid succession. The skin becomes cyanosed and finally "ashen grey," the pupils become dilated, and the subject of the experiment becomes drowsy. Dimness of vision and extreme muscular weakness are followed by unconsciousness. This process takes about 20 minutes, but when the horizontal is resumed, consciousness is immediately recovered and the symptoms rapidly subside.

Quantitative observations show that the peripheral blood flow, as estimated with the plethysmograph in the hand, is diminished, the venous pressure is less, the pulse rate more rapid, and the pulse pressure is diminished at the expense of the systolic arterial pressure. Shortly before syncope the blood flow through the hand falls to zero, the venous pressure falls below the hydrostatic level of the right auricle, the radial pulse disappears, and the blood pressure is unobtainable. Then, just when syncope is about to ensue, the pulse-rate may suddenly fall from over 120 to less than 80 per second, elimination of this drop by means of atropine makes no difference to the other manifestations, and the investigators attribute it to stimulation by anoxæmia of the cardio-inhibitory centre of the medulla. Normal blood flow, venous pressure, pulse pressure, and pulse rate are promptly restored by the horizontal position. Further experiments lead to the conclusion that not the arterioles, but the veins and venules, through loss of tone and increased capacity, are responsible for the sequence of events. It is claimed that "pooling" of blood can occur in the systemic veins as well as in the splanchnic area, and is accompanied by reflex vaso-constriction on the arterial side.

The significant feature of these experiments is the "pooling" of blood in such a way that it can be quickly returned to the circulation, and the clear demonstration, by first "removing" and then restoring the blood, that interference with the circulation is alone responsible for the symptoms. There can be little doubt that, could the experiment have been pushed further, secondary effects due to anoxæmia of the nervous system would have supervened, while lack of circulation and vaso-constriction in the periphery might well have led

to a leakage of fluid through the anoxic capillary walls and a state of "irreversible" circulatory collapse.

PRINCIPLES OF MEDICAL STATISTICS

IN clinical medicine to day there is a growing demand for adequate proof of the efficacy of this or that form of treatment. Often proof can come only by means of a collection of records of clinical trials devised on such a scale and in such a form that statistically reliable conclusions can be drawn from them. However great may be our aversion to figures we cannot escape the conclusion that the solution of most of the problems of clinical or preventive medicine must ultimately depend on them. Even those who pretend to despise this method of approach find that any assessment of success or failure which is based on fact rather than on opinion must nearly always be expressed in some numerical form—e.g., when the medical observer reports that he has treated so many cases with a favourable result in such and such a proportion, or the public health worker assesses the attack-rate on a population inoculated against some infection. But often, unfortunately, the figures used are either insufficient in number or documentation or too limited in their scope to bear the weight of the interpretation that is placed upon them. An additional difficulty is that few medical men have been trained to interpret figures or to analyse and test their meaning by even an elementary statistical technique. We have reason to believe that there is now a steadily increasing demand among both clinical and public health workers for some knowledge of that technique and a realisation that it is not much good collecting figures more or less haphazardly and then to expect a professional statistician to draw conclusions from them.

Acting upon this belief last year we invited Mr A. BRADFORD HILL, D.Sc., of the London School of Hygiene and Tropical Medicine, to prepare for our columns a series of short simple articles on such methods as his experience of medical statistics had shown him would be most useful in that field. Dr HILL's first article appeared on Jan. 2nd, 1937, and his last will be found on p. 1001 of this issue. He has succeeded beyond our hopes in demonstrating some of the ways in which investigations can be planned and figures derived from them can be analysed in order to yield fruitful results. He has chosen examples from medical publications to illustrate both the types of problem with which the medical worker is faced and the kinds of error he is most liable to make, and wherever possible he has either avoided mathematical presentation of his material or has led up to it so skilfully as to rob equations and even square roots of their traditional horrors. This consideration for those who are not mathematically minded has resulted in an exceptionally clear exposition of a difficult subject and we have had many requests to which we are happy to accede, for the reissue of these articles in book form. They will appear shortly as Vol. 3 of THE LANCET post-graduate series under the title *Principles of Medical Statistics*.

² *J. clin. Invest.* 1937, 16: 73 and 85.

ANNOTATIONS

THE TREATMENT OF ASPHYXIA
NEONATORUM

THE gibe that it takes ten years to get a new idea into a medical text book and the rest of time to get it out is not without point when applied to certain methods of treatment still recommended in some places for the severe degrees of asphyxia neonatorum. The Schultze, the Byrd and the Silvester methods are now generally regarded as valueless for the purposes of initiating respiration in an apnoeic infant and are known to be potentially dangerous, for their use may inflict trauma and cause or aggravate shock. Mouth to mouth insufflation is also of doubtful value: it may on rare occasions save a life but at the best it is an uncertain method not devoid of risk. Unfortunately no very effective and simple alternative to these unsatisfactory methods has hitherto been suggested by their critics and many obstetricians have been content, after clearing the thick mucus from the pharynx to take no action beyond keeping the infant warm in the hope that the shock from which it suffers will subside and that the slow rise of carbon dioxide tension of its blood will in a short time evoke an inspiratory effort. More active intervention is advocated by Dr R. A. Wilson of New York who on April 16th presented to the section of obstetrics and gynaecology of the Royal Society of Medicine the results of ten years' investigation of the cause and treatment of asphyxia neonatorum. The most difficult case to treat he said is the infant which has made no effort to breathe. To give oxygen and carbon dioxide by a face mask is useless and even the Drinker respirator is of so little avail that an attempt to use it may waste valuable time. Attempts to distend the lung vessels by gas pressure are in Dr Wilson's view dangerous since experiment has shown that pressures up to 18 millimetres of mercury do not lead to adequate lung expansion although they may cause rupture of the alveoli. A method recommended as useful even if it does not immediately cause respiratory efforts is intubation of the trachea followed by insufflation of oxygen under low and preferably intermittent pressure. But Dr Wilson holds intravenous injection of respiratory stimulants to be the most effective of the various means of stimulating respiratory efforts. He said that alpha lobeline and Coramine are both active in this respect but lobeline is the safer drug and he showed cinematograph films and graphic records of the respiratory efforts of new born infants obtained by a specially designed spirometer to demonstrate the remarkable effect of lobeline in initiating respiration in apnoeic infants and in augmenting feeble respirations in newly born children whose respiratory centres had been depressed by morphine or by barbiturates previously given to the mother. In barbiturate poisoning lobeline seems to be much more effective than carbon dioxide. Dr Wilson said that alpha lobeline could safely be given to infants apparently stillborn in a dosage of gr 120. The fetal cord should be clamped 8 or 9 inches from the body and the lobeline solution injected through a hypodermic needle into the umbilical vein a few inches from the clamped end. The cord should then be stripped with the fingers in order to milk the fluid into the circulating blood. The distal half of the cord should be emptied quickly and then reclamped; the remainder should be stripped at a slower rate in accordance with the

infant's needs and the response evoked. It usually took 15 seconds for the drug to reach the respiratory centre. The first effect was invariably the production of a generalized spasm of the body of the infant often with opisthotonos. This spasm was followed by vigorous respiratory efforts until these started the treatment should be conducted with the child held in the head down position.

Intravenous lobeline while of the greatest value should not be the only remedy tried. It is the result of the experiences gained by Dr Wilson and his colleagues in the treatment of 340 cases of asphyxia neonatorum the following technique has been evolved: (1) The infant's mouth and pharynx are immediately aspirated with a mucus catheter in order to remove the thick secretion and liquor which often obstructs the airway. (2) The cord is clamped, the vein injected with lobeline, the cord half stripped and clamped again according to the method described above. (3) In severe cases a tube is passed into the trachea by aid of a special laryngoscope and the air passages are then insufflated with a mixture of oxygen (80 per cent) and carbon dioxide (20 per cent). The pressure of the gas should not exceed 5 mm. of mercury. (4) The remainder of the cord is now slowly stripped the child being held head downwards. (5) After initiation of respiration and usually within two minutes time the tracheal tube is removed and replaced by a face mask through which the oxygen carbon dioxide mixture can be continued according to the needs of the case. Since prolonged apnoea may damage the respiratory centre treatment should be instituted with the minimum of delay.

These recommendations command respect because of the close study Dr Wilson has given to the experimental and clinical problems of asphyxia and because of the exact nature of his own clinical observations. The methods suggested are not new but the clear definition of their scope and value which is the outcome of wide experience has served to remove many vague impressions. The way in which lobeline is used is worthy of special note and will doubtless be tried by obstetricians in this country.

PRURITUS ANI

THE subject of pruritus ani is one of perennial interest and of no little importance both from the sufferer's point of view and also that of the medical attendant who is asked to undertake the treatment thereof. It is now well recognised that a large proportion of cases of anal pruritus are caused by a discharge at the anus. Many local conditions in the anal canal or rectum may set up such a discharge—for example anal fissures or fistulae, prolapsing hemorrhoids or polypii and any form of proctitis or colitis. The discharge dries up on removal or cure of these causative conditions and the anal irritation which is usually of a fairly mild type soon disappears too. Severe idiopathic or essential pruritus ani which was the subject of observations by J. W. Riddoch in our last issue is to be regarded as a separate disease. In Riddoch's view idiopathic pruritus ani is caused by oedema of the perianal skin following on stasis in the external hemorrhoidal veins. In a histological study of six cases evidence of oedema was found such as swelling of the prickly cells, poor staining of the nuclei and unusual prominence of the intercellular channels. In the cutis there was also obvious oedema and this was not attributed to any sort of irritant because of the absence of lymphocytosis.

infiltration The sensation of irritation is known to arise in the epidermis, and is a feature of urticaria and other skin conditions in which oedema commonly occurs. Oedema often arises from local venous stasis, and Riddoch produces clinical evidence of the way in which stasis and congestion of the veins in the external hæmorrhoidal plexus may be related to anal pruritus, he states that where this is present dilated anal veins are often to be seen through a proctoscope in the lower part of the anal canal. Riddoch suggests that certain types of treatment have proved beneficial because they have destroyed or sclerosed the veins in the anal region. Thus Ball's operation may act in this way as much as by section of sensory nerves, and the injection of various solutions, such as alcohol or hydrochloric acid, may act similarly, possibly too the injection of anæsthetic solutions in vegetable oils may have some effect, apart from the immediate anæsthesia, by causing fibrosis and venous obliteration. According to Riddoch's theory the beneficial effects which in some cases are obtained by X-ray treatment may be due to a destructive action on the blood vessels. Many observers have commented on the improvement in pruritic cases which often occurs after a *submucous* injection of a sclerosing solution such as phenol in oil, and this may be due to fibrosis of veins in the internal hæmorrhoidal plexus, and closure of the communicating veins through which back pressure can take place on the anal veins. When slight degrees of oedema (the pre-pruritic state) are present, many factors such as allergy, slight rises in temperature, or alcohol may act on the skin vessels and produce irritation, whereas the normal skin would not be affected.

Riddoch's views at least provide a useful basis for examination and treatment of the idiopathic type of pruritus, and also offer a reasonable explanation why so many different forms of treatment have, at various times, been acclaimed as beneficial in this condition. A patient with anal pruritus should certainly be subjected to the careful routine of a complete rectal examination—inspection, palpation, proctoscopy, and sigmoidoscopy. The best method of circumventing anal venous stasis must be a matter of consideration in each individual case. The treatment of the internal hæmorrhoidal areas by sclerosing injections is likely to assume a greater importance in cases of pruritus, and for the veins of the external hæmorrhoidal plexus doubtless much may be done by way of operation (excision of skin ridges or tags with the underlying veins) or by injection of irritant solutions which have been proposed from time to time. These include alcohol, quinine urea, hydrochloric acid, castor oil, phenol in oil, and the various anæsthetic solutions in oil, most of which, it may be noted, contain benzyl alcohol.

HOSPITAL KITCHENS

THE importance of providing good, appetising, well served food for hospital patients was emphasised by Miss R. Whitaker, principal of the Gloucestershire Training College of Domestic Science in a Chadwick lecture delivered in London on April 15th. Failure in the dietary department, she said, "delays convalescence and unfavourably moderates its completeness." The provision of suitable food is, however, by no means simple. Good food, well cooked, may suffer deterioration in its transport from the kitchen to the bedside, and many cooks in institutions are unfairly hampered by lack of the conditions in which alone a satisfactory diet can be produced. Miss Whitaker laid special stress on the necessity of well-

planned kitchen offices, so that raw materials may enter the building as near as possible to the stores, and each item forming part of the meal may "travel steadily forward through the various processes of preparation, with no backward movements and as little cross tracking of workers as may be, until the finished product is assembled in the hot or cold closets of the servery." Not only must the large apparatus be properly placed, but the small tools should also be as far as possible within reach of the worker, who should be able to sit at her duties by the provision of knee hole accommodation in her table. Ventilation and lighting are important. Cross-ventilation is essential, and alternative methods should be available. The best lighting of a kitchen, Miss Whitaker said, is literally the cheapest. Natural light should be admitted to the greatest possible extent, while artificial light should be adequate, without glare, and placed to fall upon the work and not upon the worker. A combination of gas and electricity, with the addition of steam, will probably give the greatest efficiency in fuel.

STAPHYLOCOCCI AND URINARY CALCULI

THE ætiology of urinary calculi is still an unsolved problem. The part played by infection is however well recognised and some modern authorities indeed are even doubtful whether urinary lithiasis exists at all unaccompanied by infection. H. P. Winsbury White, who has recently reviewed the subject, points out that this conclusion has been reached chiefly as the result of improved technique, whereby organisms may be found more readily in the urine and actually identified in the nuclei of the calculi themselves. These investigations have particularly incriminated the staphylococcus. J. Swift Jørgensen repeatedly emphasises the importance of staphylococcal infection of the urine, and recently John Hellström³ has written a monograph on the subject of staphylococcus stones. This study is based on 90 cases, all observed personally by himself, thoroughly investigated, and followed up for varying periods, 16 of them for more than ten years. Only cases in which staphylococci were found in the stone without a large admixture of other organisms are included in the series. The stones were examined for cocci by dissolving out the inorganic constituents with hydrochloric acid, and then either making smears or cutting sections. Cultures from the urine showed that by far the commonest organism was the *Staphylococcus albus*. It is estimated that about 14 per cent. of all urinary calculi are due to staphylococcal infection.

The treatment of these conditions is unsatisfactory because the infection is so difficult to eradicate. The stones themselves have mostly to be removed by operation, either by themselves or with a kidney. Hellström's operative mortality was less than 1 per cent, but his recurrence rate was 38 per cent. The percentage cured of both stones and infection was 52. Seventeen out of the 90 patients avoided operative treatment by passing their stones, of these only 1 suffered a recurrence, but 8 remained infected. It is apparently even more difficult to treat the infection than the stone. Acidification of the urine, vaccination, and most of the so-called "urinary antiseptics" are ineffective. Hellström obtained the best results with neosalvarsan and also favours direct irrigation of the renal pelvis.

² Stone and Calculous Disease of Urinary Organs, London, 1934.
³ Acta chir. scand. 1924, 79, Suppl. 6.

The actual method of formation of staphylococcus stones is not thoroughly understood. Many of the factors concerned in stone formation in general are probably at work, such as disturbances of the colloid-crystalloid equilibrium of the urine. It is possible that conglomerations of the cocci serve as nuclei for the stones to form around, or the cocci may act indirectly by providing a kind of protein that upsets the colloid-crystalloid equilibrium. The large masses of cocci found in some of the stones tends to support the former hypothesis. Another factor may be the effect of staphylococci on the pH of the urine, for many staphylococci (especially *S. albus*) have the power of forming ammonium carbonate from urea. M. S. S. Earlam⁴ and others have shown that by no means all staphylococci associated with urinary calculi have the power of splitting urea and moreover most patients with staphylococcus stones have acid urine. Hellström observes however that in all cases examined by him the staphylococci on cultivation in urine turned it strongly alkaline and suggests that an artificial solution of urea is not a fair substitute for the urine itself. He maintains also that he has often observed a difference between the reaction of the bladder urine and that of the urine in the immediate vicinity of a renal calculus.

NATALITY AND MORTALITY IN THE U.S.A.

Two volumes corresponding to the annual reports of the Registrar General of England and Wales are issued annually by the Bureau of the Census of the United States. One deals with the year's births still births and infant mortality the other with the statistics of the mortality registered. The reports for the year 1934 have recently been issued.⁵ The registration area first established for deaths in 1880 for births in 1915 has slowly but steadily widened. For mortality statistics States have been admitted only on the basis of approximately complete registration of deaths (at least 90 per cent of all deaths) and when the data have shown that the deaths are recorded properly under adequate registration laws. Texas admitted in 1933 has been the last State to satisfy these criteria. The present reports therefore relate for the first time to the whole of the United States. Supplementary returns are also provided for the territory of Hawaii Puerto Rico and the Virgin Islands. In 1934 the estimated population of the United States was 126 626 000 and the total numbers of births and deaths registered amounted to 2 187 638 and 1 396 903 giving a birth rate of 17.1 per 1000 inhabitants and a crude death rate of 11.0. The natural increase of population it will be noted was rather more than three quarters of a million persons. The infant mortality rate was 60 per 1000 live births and in addition 78 503 stillbirths (7.6 per 100 live births) were notified. This enormous mass of material is tabulated in these two reports in considerable detail attention being paid to such factors as urbanisation season colour or race sex and age and cause of death. Statistics are given of plural births (there were in 1934 six cases of quadruplets all born alive) and of birth rates by age of mother information we are still waiting for in this country. In view of the public interest in road accidents two special accident tables are included in the mortality report. In 1934 just over 36 000

deaths were attributed to motor vehicle accidents in the registration area an increase of over 5000 deaths above the average for the three previous years. For those desirous of making an excursion into the vital statistics of the United States study of these two reports is essential.

SURGICAL TREATMENT OF HYPERTENSIA

Page and Heuer¹ describe a small series of cases—17 in all—treated for hypertension by bilateral division of some or all of the anterior nerve roots dorsal VI to lumbar II. The grounds for this procedure are that it cuts off vasoconstrictor impulses to the splanchnic area and this is followed by vasodilatation in this area with a resulting fall of blood pressure. That this is the immediate effect of the operation seems clear. But in most of these few cases at any rate the drop in blood pressure appears to have been merely temporary and at the end of the period of observation (maximum 37 months) it was seldom much lower than before the operation. The chief improvement observed was in the subjective symptoms and as the authors say that a strong element of neurosis was obvious in many of the patients it seems likely that equal improvement might have been attained by less spectacular means. The operation in itself seems to have had no ill effect upon the functions of the heart or kidneys but it does not appear from this series of cases that any improvement in renal function is to be expected as a result of the lowering of blood pressure. This is in direct contradiction to results reported by Freyberg and Peet² in 48 cases of hypertension treated by bilateral section of the splanchnic nerves. In such patients as responded by a considerable fall of blood pressure these workers found decided improvement in the renal function as measured by the concentration and urea-clearance tests. But in this series again the results of the operation were very variable and as a rule the blood pressure level after an initial fall showed a tendency to rise to or even above the pre-operative figure. Such results indeed raise serious doubts whether severe operations upon the nervous system are a justifiable means of treating hypertension.

CHRONIC MILIARY TUBERCULOSIS IN CHILDREN

As long ago as 1845 Waller in Germany noted that miliary tuberculosis of the lung is not always fatal and radiography has now made it recognizable before death. Dr R. H. Fish³ is thus able to describe four cases with recovery (as well as six fatal ones) observed at High Wood Hospital Brentwood which receives all children with pulmonary tuberculosis requiring treatment under the London County Council tuberculosis scheme. In the fatal cases the illness varied in duration from 51 to 11 months from its demonstration radioscopically. Four of the six showed undoubted though temporary improvement and post mortem examination of the tubercles which contained live tubercle bacilli revealed all stages of healing. The four non fatal cases were similar to the others except in their recovery. Persistent but mild pyrexia was almost constant but it was punctuated by occasional rises perhaps representing waves of bacillæmia arising from massive tuberculous glands in the upper mediastinum. A slight cough was often present.

³ *Arch. Dis. Child.* February 1937 p. 1.

and sometimes a few râles, but no gross signs were found in the chest. Tubercle bacilli were occasionally demonstrated in the sputum, but recourse to gastric lavage and guinea pig inoculation was commonly necessary. The Mantoux reaction was usually positive on using 0.1 c.c. of 1 in 10,000 old tuberculin and always in 1 in 1000 dilution. Radiography showed the characteristically diffuse and mottled appearance of the lung. In the four non-fatal cases, and some of the fatal ones, extrapulmonary lesions were coexistent.

In treatment, rest is of paramount importance, and it must be continued until the stippling has disappeared, which happens when the tubercle is replaced by fibrous tissue. All these patients were treated on open air balconies, and Dr Fish gave them gold in the form of Solganal B, which he thought beneficial. The prognosis proved as difficult in this type of tuberculosis as in others, and cases apparently of the worst type recovered.

RATIONAL SALINE THERAPY

THE intravenous injection of common salt solution has been recommended for a variety of conditions. Some of the recommendations appear contradictory—for example, the use of "normal" or hypertonic saline for cure of the anhydremia of shock and hæmorrhage and as a treatment for anuria in which fluid retention may be taking place. The occasional efficacy of intravenous therapy can be explained by blood analyses. Root¹ describes two cases in which intravenous hypertonic saline restored the urinary flow in patients with only one kidney. Both patients had anuria with increasing nitrogen retention and low blood chlorides, one as a result of vomiting and the other from excessive sweating. After intravenous therapy and restoration of the urinary flow the blood chemistry became normal and recovery followed. An example is given of the calculation of the chloride deficit and the exact amount of salt solution to remedy this. No doubt if these methodical analyses could be conducted on all patients before the administration of intravenous solutions, such brilliant results might be achieved more often. There seems to be no very good reason why a vein should be preferred to the alimentary canal for salt or fluid replacement, especially if reasonably early blood analyses are done to reveal the condition before it becomes acute. If clinician and laboratory were always able to work more closely together in these circumstances many lives would be saved.

THE BLOOD PICTURE AFTER INDUCED FEVER

THE account on p. 1007 of the congress on artificially induced fever shows to how many different uses this treatment is now being put in America. Its effect on the hæmopoietic equilibrium is thus of considerable moment. F. H. Krusen has recently summarised² his observations on a large group of patients. The patient's body was exposed from 3-7 hours in hot circulating humid air varying from 145°-150° F., the humidity being kept constant. Samples of blood were taken from each patient immediately before and immediately after each fever treatment. The disease for which fever therapy was given appeared to be without effect on the character of the response. Similar changes were noted in both venous and capillary blood, so it may be concluded that such changes represent a fundamental alteration in hæmo-

poietic equilibrium and are not dependent upon superficial hyperæmia. Average venous counts on 100 patients before treatment gave a leucocyte count of 7100 per c.mm., while after fever the count was 11,300 per c.mm. This increase was dependent upon an increase in polymorph cells. No change that was significant was found in the Arneth count. The red cell count was unaltered. The author believes therefore, that there is a true increase in circulating white cells, since there is no evidence of concentration of the blood and the white cell increase appears to affect one cell type only. Rather more elaborate studies of the same problem have been made by Dr M. M. Hargraves, who adds a note to Dr Krusen's paper. Dr Hargraves followed his patient for 20 hours after the onset of fever with half hourly blood counts. He found a response so constant that he characterises it as a "febrile hæmogram." There is a post-febrile leucocytosis, the duration and extent of which is an individual affair related to the duration and height of the fever. The peak of leucocytosis is dependent on a polymorphonuclear increase and often goes as high as or higher than 40,000 leucocytes per c.mm. At this stage the younger cells as shown by an Arneth count are increased, evidence it is believed of bone marrow delivery rather than of redistribution. As the polymorph peak declines, the total count is sustained, at least to some extent, by an influx of monocytes. The lymphocytes reappear in normal numbers only towards the end of the period. These figures, Hargraves suggests, confirm Krusen's observation which was correct for the time of sampling but usually missed the peak of the response. Apart from their own interest these figures emphasise again how rapidly changes in the white cell count occur, rendering single of far less value than serial observations.

OBSTETRICAL EMERGENCIES

Prof Farquhar Murray's idea of a local emergency service for difficult childbirth is now bearing fruit. It is some twelve years since he began to work out a way of providing the accoucheur with the needed assistance whenever the unexpected difficulty presented itself. In 1929 he advocated¹ the organisation of emergency services, especially in industrial areas, and in 1935, with the co-operation of the medical officer of health, he initiated such a service in Newcastle upon Tyne, which was nearly the first of its kind, something similar having been tried in Lanarkshire two years previously. In that year a local Newcastle journal gave a graphic account of how the efficiency of the service was tested. Prof Murray with an accoucheur and the M.O.H. sent an emergency call from a house in a Newcastle suburb, and within 15 minutes of the call being made a nurse was on the doorstep, followed in another minute by the gynæcologist, who had travelled three miles and was only summoned after the first man at the rota was found not to be at home. The procedure is simply this: the doctor or someone acting for him telephones to the maternity hospital where the outfit is kept, asking for the service to be put in motion, and giving name and address of patient and name of consultant desired. The hospital rings up the consultant named and if he is not at once available one of the others on the panel of four takes his place. He goes direct to the patient's house unless this is outside the five mile radius, in which case he calls to pick up the nurse and outfit. For local cases the hospital telephones to a taxi rank and sends the

² *Amer. J. med. Sci.* 1937 193, 470.

¹ *Brit. med. J.* 1929 1 601.

nurse and outfit direct to the patient's house. The agreed charges for Newcastle-upon-Tyne are consulting fee two guineas, operation fee four guineas, nurse and outfit one guinea, taxi charges extra. Outside Newcastle the service is now available in Gosforth, Newburn, Tynemouth, West Hartlepool, and generally throughout the counties of Northumberland and Durham. During the eighteen months it has been in operation some 20 emergency cases have been attended, in a number of which Prof. Murray is assured that lives have been saved.

Just over a year ago a similar flying squad was inaugurated at the Birmingham Maternity Hospital by co-operation between its honorary staff and the medical officer of health, the underlying principle of the scheme being to bring the resources of the hospital to the patient's bedside in case of serious obstetrical complications where transport would be likely to impair the chance of recovery. The equipment is supplied by the public health authority and the scheme in general is planned on the northern model. The working has been found quite simple. The practitioner in charge of the case sends two messages—one to the consultant, the other to the maternity hospital which is in close touch with the St. John Ambulance Service. Within a few minutes a senior nurse arrives with equipment which includes blankets, hot bottles, bags containing surgical requirements and drugs appropriate for any emergency. The ambulance stays at the door in case the patient should be in a fit condition to be moved but in practice it generally does no more than take the apparatus and nurse back to hospital. During the short period in which it has been in use the flying squad has admittedly been instrumental in providing help without which the parturient mother could not have come through safely.

THE JOURNAL OF THE UNIVERSITY OF MANCHESTER

The first issue of the *Journal of the University of Manchester* represents a venture which must be successful. The journal will be recognised by all the members of the university as forming a common bond between the graduates providing them with topical news and interesting personalities as well as information on developments in university policy. If future issues maintain the standard of No. 1 Vol. I the journal will be welcomed not only by those whom it is specially designed to please but by all interested in university education. The recent growth of the University of Manchester and the part to be played in the future by university education are set out in two opening essays by Sir Ernest Simon, treasurer of the university, and Prof. Godfrey Thomson, whose Ludwig Mond lecture delivered last autumn at Manchester is now reproduced. Prof. Thomson closes with these words which all who take heed to the meaning and needs of education will endorse—

The only hope for unity permanent unity among mankind is through the rule of intelligence through the cultivation by an education proper to each of the intelligence of all. The schoolmaster is right who considers that his sole business is to lead his pupils to see truth clearly and who holds that that is in itself character training and the only character training the school may lend itself to if it is to refrain from sowing party or class colour or race or prejudice of whatever kind but is to serve civilisation and all mankind.

The university is the next stage to the school, and this broad social view is even more obvious in university training. The new journal exhibits the

University of Manchester as a centre of liberal progress and its graduates will welcome it and it is a present to them for it will be supplied without charge to them and the friends of the university on application to the Manchester University Press, Wright-street, Manchester.

LYMPHATOLOGY*

A SYSTEMATIC study has been pursued for many years at the anatomical institute of the University of Kyoto into properties of lymph and the lymphatic system for which subject they use the convenient term lymphatology. Recent results are recorded in a series of papers numbered 76-101 by a group of workers under the general direction of Prof. S. Funakoka. The rabbit has been the experimental animal throughout and lymph was obtained from afferent and efferent trunks of the popliteal gland from the gland capsule itself and from lymphatics of liver and intestine by simple collection or perfusion. In order to collect lymph at these sources special techniques have been developed. Many of the workers have exploited the method devised by Prof. M. Watanabe under the guidance of Funakoka by means of which all lymphoid tissue is removed from popliteal glands and lymph is collected in the shell of the capsule that remains behind. Lymph obtained by this means is referred to as

Brunnelymph to distinguish it from that obtained from afferent and efferent trunks. An improved method for gaining access to the efferent popliteal lymphatic has been devised by Y. Yoshida. It consists in constricting the efferent vessel together with the nutrient artery by means of a ligature till it is distended with stagnant lymph. Then when it is easily visible a large sized hypodermic needle is passed into its lumen, a second ligature is passed round the needle and the first is removed. This manoeuvre diminishes damage to blood-vessels in the gland and the danger of contamination of lymph by cells and serum. A method for obtaining liver lymph is described by Funakoka and S. Sumiya. Various quantities of the lymph which was obtained are given in a Table but unfortunately no mention is made of the time taken to collect these amounts. In this respect the contribution by K. Okamoto is especially interesting for he gives the following details: the duration of obtaining peripheral lymph depends upon the time of year. It is more difficult in April and at the end of October (in Japan) by the Brunnelymph method the quantity collected in the first half hour varies from 0.3-1.5 c.c. and the mean is 1.2 c.c. per hour. The limb from which the flow was obtained was normal, was not massaged, and the animal was loosely held round the abdomen. Details such as these are conspicuously lacking in the form in which most of this Japanese work is available to European and American readers and they are of far greater interest than tabulated results of scantily described

used in an examination of normal and retrograde lymph flow

Part II ends with a concise summary by Prof Funaoka of chemical investigations done at his institute as well as elsewhere and his promise to develop certain special themes in future volumes

THE TAVISTOCK CLINIC'S APPEAL

THOSE who were associated with the institute of medical psychology now situated at Malet-place, WC1, in its early days at Tavistock square, will rejoice that the old name is to be restored. This welcome change comes, however, at a time of severe crisis for the clinic. It is one of the very few institutions which gives psychotherapy to out-patients suffering from neuroses and psychoneuroses, and provides post graduates with opportunity to study the various methods employed by its staff. It promotes many courses of lectures and demonstrations on mental health for medical and lay workers and also maintains a child guidance clinic. All this work is supported entirely by voluntary generosity, the medical staff are either unpaid or receive very small honorariums.

The council of this excellent clinic are now faced with serious shortage of money. A year ago they hoped almost immediately to build and equip a hostel for in patients in the neighbourhood, but they received so little financial support that they did not feel justified in carrying out the plan. The lease of the present hostel was due to expire in a few months but it has fortunately been possible to arrange for an extension until midsummer next year. This is, however, only a respite and financial help is none the less urgently needed. The council say in their annual report for 1936 that unless the situation is promptly relieved they will be forced to curtail the clinic's work and to abandon its promising extension. It would be tragic if the development of the work of this clinic were thus hindered. In many other countries the problem of the mentally unfit is dealt with on a much larger scale, for example, Vienna has a dozen counterparts of the Tavistock Clinic. It would be a veritable disgrace if this pioneer clinic, which is even now quite inadequate in quantity though not in quality to meet the needs of London alone, failed to find support. It is doing fine work and has large numbers of patients clamouring for help. The council are making a special appeal to the industrial community, and especially to large employers of labour. There is every reason why they should get a response, since one third of the incapacity of employed persons in this country is attributed to functional nervous disorder, and in addition, thousands of workers who are not actually incapacitated have their efficiency much reduced by neuroses, with an aggregate loss to the nation's industry, which is not easy to measure but is certainly severe.

ETHYL STRYCHNINE AS A RESPIRATORY STIMULANT

THE important uses to which a drug might be put which had the power to exert a stimulating action directly on the medulla need no demonstration. Respiratory arrest during anaesthesia may be mentioned merely as one example. Experiments which their authors believe establish the value of ethyl strychnine as such a drug have now been described by M. Aiazzi Mancini and L. Donatelli.¹ They point out the striking difference between the

effects of strychnine and those of ethyl strychnine. The former, which was at one time much recommended for injection during surgical emergencies associated with shock, has long been disapproved of in these circumstances, the researches of Crile having had much to do with forming the conclusion that strychnine in spite of its stimulant power is exhausting and dangerous when applied to an acutely depressed nervous system. The most commonly employed restoratives for failure of breathing are at the moment carbon dioxide, with or without oxygen, Coramine, and lobeline. The authors to whom we have referred believe that ethyl strychnine may prove superior to these clinically as it has in their experimental work. Previous observers working with strychnine have maintained that respiratory depth is increased by injection of the drug only if the stage of convulsion is reached. Ethyl strychnine, on the other hand, is able to stimulate the medullary centre in doses which do not modify spinal activity. Moreover its toxicity to a normal animal is only a twentieth of that of strychnine. In animals under narcotics and anaesthetics ethyl strychnine was found to increase greatly the depth of breathing, without having much effect on the rate. In doses of 0.05 to 0.25 mg per kg of body weight the action is prolonged and unaccompanied by any convulsive effect. Undesirable symptoms were produced only if the drug was injected into a vein. The authors insist therefore that ethyl strychnine should be used intramuscularly, or under the skin. The doses needed to stimulate animals poisoned by narcotic or anaesthetic were of course much greater than those which stimulated respiration in the normal animal.

MEDICINE STAMP DUTY

In the Budget the Chancellor of the Exchequer has found the extra money he needed without action on the recommendations of the Select Committee on Medicine Stamp Duties, which showed him how to add £3,000,000 or thereabouts to the revenue. Till for the time being the report is shelved, but it is not likely to be forgotten. "I am having the recommendations examined," said Mr Chamberlain, "but in view of the very complex issues involved and the existing strain on the time of Parliament I am not proposing to introduce legislation on this subject in the Finance Bill this year." Such a source of revenue as exposed by the committee cannot be overlooked indefinitely, but, in the meantime, other means of keeping the traffic in proprietary medicines within reasonable bounds may be explored.

WE regret to announce the death on April 18th of Dr Archibald Donald, emeritus professor of obstetrics and gynaecology in the University of Manchester.

MEDICAL SERVICES IN U.S.S.R.—7528 million roubles (nominally about £200 millions) is allocated for the State budget of the Soviet Union for health protection in 1937, as against 5803 million roubles in 1936. It includes an expenditure of 1000 million roubles on building. The number of hospital beds in 1937 will be brought up to 619,800 as against 564,000 in 1936, maternity beds to 11,078 as against 6000. The public nurseries will be extended in the urban areas to provide places for 609,000 children as against 464,000 in the previous year, and rural areas to provide places for 570,000 children against 378,000. Sanatoriums and health resorts in 1937 will provide 95,000 beds as against 91,500 in 1936, while the number of beds at the rest homes run by the trade unions will be increased from 90,300 to 105,000.

PRINCIPLES OF MEDICAL STATISTICS

XVII.—CALCULATION OF THE CORRELATION COEFFICIENT

THE correlation coefficient r is most easily calculated from the formula $r = \frac{\text{mean of the values of } (x - \bar{x}) \text{ minus mean of the observations of } y}{\text{standard deviation of } x \times \text{standard deviation of } y}$ Or in the symbols previously used,

$$r_{xy} = \frac{\text{Sum of values of } (x - \bar{x})(y - \bar{y})}{n\sigma_x\sigma_y}$$

The Ungrouped Series

Suppose for instance we have measured on twelve persons their pulse rate and their stature and wish to measure the degree of relationship if any between the two by means of the correlation coefficient. The twelve observations are given in columns (2) and (3) of Table X A.

TABLE X A

Indi- vidual No	Pulse rate in beats per minute	Height in inches	x^2	y^2	$x - \text{Mean } x$	$y - \text{Mean } y$	$(x) \times (y)$	$\frac{x \times y}{n}$ (1) $\times$ (3)
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)
1	63	65	3,844	4,225	-10	+1	+10	1.16
2	74	65	5,476	4,225	+2	+1	+2	1.810
3	80	73	6,400	5,329	+8	+4	+32	5.810
4	59	70	3,481	4,900	-13	+1	-13	4.150
5	65	69	4,225	4,761	-7	0	0	1.485
6	73	66	5,329	4,356	+1	-3	-3	4.818
7	78	69	6,084	4,761	+6	0	0	5.382
8	80	71	6,400	5,041	+14	+1	+14	6.000
9	61	74	3,721	5,476	-6	+3	-18	4.668
10	68	71	4,624	5,041	-4	+2	-8	4.878
11	75	68	5,625	4,624	+3	-1	-3	6.100
12	86	67	7,400	4,489	+13	-2	-26	5.360
Total 12	864	828	62,980	57,194	0	0	-10	59.597
Mean values	72	69	5,183.33	4,766.17	—	—	-1.58	4.966 12

The standard deviations can be found as shown before by squaring each observation finding the mean of these squares subtracting from it the square of the mean and taking the square root of the resulting figure. The standard deviation of the pulse rates is therefore $\sqrt{5248.33 - (72)^2} = 8.02$

and of the height is $\sqrt{4766.17 - (69)^2} = 2.27$. The deviation of each individual's pulse rate from the mean pulse rate of the twelve persons is given in column (6) and of each height from the mean height in column (7). If there is any substantial (and direct) correlation between the two measurements then a person with a pulse rate below the mean pulse rate ought to have a stature below the mean height one with a pulse-rate above the mean rate ought to have a stature above the mean height. (If the association is inverse positive signs in one will be associated with negative signs in the other.) Inspection of the figures suggests very little correlation between the characteristics. For the numerator of the correlation coefficient formula we need the product of the two deviations shown by each person. These are given in column (8). Their sum is -10

and their mean is therefore $-10/12 = -1.58$. The coefficient is reached by dividing this mean product value by the product of the two standard deviations—namely 8.02×2.27 and gives a value of -0.09 . In other words in these twelve individuals the pulse rate and stature are not related to one another.

In the example taken this is a satisfactory mode of calculation because the mean pulse rate and the mean height are whole numbers and also the original measurements are whole numbers. It is then easy to calculate the deviation of each observation from its mean. But if decimals had been involved the deviations would have been troublesome to calculate. In that case it is easier to avoid altogether using deviations and to multiply directly the pulse rate of each person by his stature as in column (8) applying a correction at the end to the resulting mean value. The correction necessary is this from the mean value of the products thus found we must subtract the product of the two means—i.e. the product of the distances between the points from which we chose to measure the deviations and the points from which we ought to have measured them. In the example taken this gives $4060.42 - 72 \times 69 = -1.58$ or the same value as was previously reached by working with the real deviations from the means.

This is the simplest and best method of calculating the two standard deviations and the correlation coefficient between the characteristics in anything up to 50-60 observations. With a larger series of observations finding the individual squares and products becomes progressively more laborious and it is better to construct a grouped correlation table.

The Grouped Series

As an example we may take for each of a number of large towns in England and Wales (1) a measure of the amount of overcrowding present in a given year and (2) the infant mortality rate in the same year. We wish to see whether in towns with much overcrowding the infant mortality rate tends to be higher than in towns with less overcrowding. We must first construct a table which shows not only how many towns there were with different degrees of overcrowding but also their associated infant mortality rates.

Table X B gives this information. The town with least overcrowding had only 1.5 per cent of its population living more than 2 persons to a room (this being used as the criterion of overcrowding); the percentage for the town with most overcrowding was 17.5. The lowest infant mortality rate was 37 deaths under 1 per 1000 live births and the highest was 110. Reasonably narrow groups have been adopted to include those maxima and minima and each town is placed in the appropriate cell. —e.g. there were 5 towns in which the overcrowding index lay between 1.5 and 4.0 and in which the infant mortality rates were between 36 and 40 there were 2 in which the overcrowding index lay between 10.5 and 13.5 and in which the infant mortality rates were between 86 and 90. (If a very large number of observations is involved it is best to make a separate card for each town person or whatever may have been measured, putting the observed measurements on the card always in the same order. The cards are first sorted into their proper groups for one characteristic (overcrowding) and then each of those packs of different (overcrowding) level is sorted into groups for the other characteristic (infant mortality). The cards in each small pack then relate to a particular cell of the table.)

Table X B shows at once that there is some association between overcrowding and the infant mortality-rate, for towns with the least overcrowding tend, on the average, to show relatively low mortality rates, while towns with much overcrowding tend to show high mortality rates. The table is, in fact, a form of scatter diagram.

TABLE X B
Overcrowding and Infant Mortality Example of Correlation Table

Infant mortality rate	Percentage of population in private families living more than two persons per room						Total
	1 5-	4 5-	7 5-	10 5-	13 5-	16 5-19 5	
36-	5						5
40-	9	1					10
50-	10	4					16
66-	4	7	1			1	18
76-	2	5	4	2	1		13
86-		2	2	2		1	7
96-		1	2	2	1	1	7
106-116		1		1			2
Total	30	21	14	8	2	3	78

To calculate the coefficient of correlation we need (1) the mean and standard deviation of the overcrowding index, (2) similar figures for the infant mortality rate, and (3) for each town the product of its two deviations from the means—i.e. (overcrowding index in town A minus mean overcrowding index) $\times$ (infant mortality rate in town A minus mean infant mortality rate). In other words we wish to see whether a town that is abnormal (far removed from the average) in its level of overcrowding is also abnormal in the level of its infant mortality rate. In calculating the means and standard deviations of the two distributions we can entirely ignore the centre of the table, we have to work on the totals in the horizontal and vertical margins. The method is shown in Table X C.

TABLE X C
Overcrowding and Infant Mortality Calculation of Correlation Coefficient

Infant mortality rate		Percentage of population in private families living more than two persons per room						Total
		R U 1 5-	4 5-	7 5-	10 5-	13 5-	16 5-19 5	
R U	W U	W U -2	-1	0	+1	+2	+3	
36-	-3	5 (+30)						5
46-	-2	9 (+36)	1 (+2)					10
56-	-1	10 (+20)	4 (+4)	1 (0)			1 (-3)	16
66-	0	4 (0)	7 (0)	5 (0)	2 (0)			18
76-	+1	2 (-4)	5 (-5)	4 (0)	1 (+1)	1 (+2)		13
86-	+2		2 (-4)	2 (0)	2 (+4)		1 (+6)	7
96-	+3		1 (-3)	2 (0)	2 (+6)	1 (+6)	1 (+9)	7
106-116	+4		1 (-4)		1 (+4)			2
Total		30	21	14	8	2	3	78

R.U. = Real units W.U. = Working units

For instance we see from the right hand totals that in 5 towns the infant mortality rate was between 36 and 46 in 10 between 46 and 56, in 16 between

56 and 66, and so on. Of this distribution we want the mean and standard deviation. As shown previously, these sums are more easily carried out in "working units" instead of in the real, and larger, units. In these units we have 5 towns with an infant mortality rate of -3, 10 with a rate of -2, and so on. In working units, therefore, the sum of the rates is +5 and the mean rate is $+5/78 = +0.06$. The mean in real units is, then, 71 (the centre of the group opposite 0) $+ 0.06 \times 10$ (10 being the unit of grouping) $= 71.6$. To reach the standard deviation we continue to work in these units. Measuring the deviations from the 0 value instead of from the mean there are 5 towns with a squared deviation of $(-3)^2$ and these contribute 45 to the sum of squared deviations, there are 10 towns with a squared deviation of $(-2)^2$ and these contribute 40 to the sum of squared deviations.

In working units the sum of squared deviations from 0 is thus found to be 237. The mean squared deviation from 0 is $237/78 = 3.0385$ and from this, as correction for having measured the deviations from 0, we must subtract the square of 0.06, the value from which we ought to have measured the deviations. The standard deviation of the rates in working units is therefore the square root of $3.0385 - (0.06)^2 = 1.742$, and in real units is $1.742 \times 10 = 17.42$.

We can now work in just the same way on the distribution of overcrowding—there are 30 towns whose overcrowding index in working units was -2, 21 whose index was -1, and so on. This gives a mean and standard deviation in working units of -0.77 and 1.329 , and in real units of 6.7 and 3.49 . In this there is nothing new, the process was given in full in Section XVI.

We now need the product of the deviations from the means for the numerator of the correlation coefficient. This is easily reached by continuing to measure the deviations in working units from the 0 values and making a correction as usual at the end.

For instance, there are 5 towns the deviation of which is -2 in overcrowding and -3 in infant mortality. The product deviation is therefore +6, and as there are 5 such towns the contribution to the product deviation sum is +30. Each of these values can be written in the appropriate cell (they are the figures in parentheses in Table X C). Their sum is +107 and the mean product value is $+107/78 = +1.3718$. These deviations in working units were measured from the two 0 values whereas they ought to have been measured from the two mean values, +0.06 and -0.77, therefore as correction we must subtract from +1.3718 the product of +0.06 and -0.77 (as in the ungrouped series, the correction is the product of the distances between the points from which we chose to measure the deviations and the points from which we ought to have measured them). The numerator of the coefficient is therefore $+1.3718 - (0.06 \times -0.77)$, and the denominator is the product of the two standard deviations, so that

$$r = \frac{+1.3718 + 0.0462}{1.742 \times 1.329} = +0.61$$

(It may be noted that as the numerator is in working units the standard deviations must be inserted in the working units.)

There is we see a fair degree of correlation between overcrowding and the infant mortality rate, but at the same time Table X B shows that with towns of the same degree of overcrowding there are considerable differences between the infant mortality rates. The standard error of the coefficient is $1/\sqrt{n-1} = 1/\sqrt{78-1} = 0.11$, as the coefficient is more than five times its standard error it may certainly be accepted as "significant".

The calculation is very much speedier with the observations thus grouped and little change has been

made in the values reached as the following figures show—

	Grouped series of Table X n.	Same 78 observations ungrouped
Means—		
Overcrowding	6.7	6.6
Infant mortality	71.6	71.0
Standard deviations—		
Overcrowding	3.99	3.74
Infant mortality	17.1	17.3
Correlation coefficient	+0.61	+0.59

The regression equation is—

$$\text{Infant mortality minus } 71.6 = +0.61 \frac{17.4}{3.99} (\text{over}$$

crowding index minus 6.7) which reduces to—

Infant mortality = 2.66 overcrowding index + 53.78 (It must be noted that the values in real units must be inserted in this equation.) In other words the infant mortality rises according to these data by 2.66 per 1000 as the percentage of the population overcrowded increases by 1

A. BRADFORD HILL.

SPECIAL ARTICLES

BRITISH HEALTH RESORTS ASSOCIATION

A MEETING of the British Health Resorts Association was held at Skegness on Saturday last. The conference was well attended and the various advantages that might be derived by the sick, the convalescent, and the public from the facilities offered at the different centres in this country were brought out. The congressists were the guests of the municipality.

Lord Meaton the president of the association spoke of the inception of the movement and of its development from a winter in England movement into a body not only interested in presenting the claims of British resorts on to the attention of the medical profession and the public but also in promoting the study of the climatic and other conditions which made these resorts suitable or perhaps unsuitable as health seekers at different times of the year must have resorts selected for them. He pleaded for greater support by local authorities whose interests the association was unselfishly serving but noted the steady improvement in hotels to which he thought the notion of the association had contributed. Speaking from personal experience in many countries he held that the British hotels had nothing to fear from comparison if like were compared with like.

The chairman of the Skegness urban district council Mr J Crawshaw presided at the first session dealing with

Industry and the Health Resort

Mr A J Peterson managing director of the Spirella Company of Letchworth spoke as an employer in a firm which had made complete arrangements for the welfare of its employees. As most of the users of health resorts he said, were connected with industry it was important for employers who desired to be progressive should be told more of the advantages of these resorts for the workers. He stressed the point that with payment for holidays a movement which was advancing there would be great opportunities for health resorts placed in proximity to the centres of industry. He said that there should be talks in the factories on how holidays could be used so that holiday makers could get the best value out of them.

Mr Ernest Bevin general secretary of the Transport and General Workers Union said that the provision of holidays with full pay for the workers was one of the principal struggles of the movement he represented. The different treatment of staff public servants and others employed in more favourable occupations as against the actual

workers formed a serious grievance. Since the war the more enlightened employers were realising that the granting of holidays with pay was not only an advantage to the working person and his family but to industry itself. Unpaid unemployment moreover had risen periodically so that the whole question of what might be termed the contractual period for labour had been brought within the realm of practical politics and the Government had now set up a committee, of which he was himself a member to consider the whole problem.

THE AMENITIES OF HEALTH RESORTS

There was need for the creation of an industry to cater for the holiday needs of the workers there should be a scientific study of the whole matter and the provision of holidays for the workers would open an avenue of employment for thousands of others. He held that the British health resorts had not taken a sufficiently enlightened view to meet the requirements that this new development would entail. It had been demonstrated that a great set off against the cost of holidays to industry generally was the decrease in sick leave and absenteeism. The English climate was not an easy one for which to cater but the kind of shelter put up along sea fronts, with a glass partition in the centre was quite inadequate to meet the weather changes and yet these shelters were an absolute necessity if visitors were to derive the benefit of the sea air. And when holiday resorts were planned there must be a real drive to secure a better standard of accommodation. Although hot and cold running water in every room was so readily advertised in thousands of houses, which the workers now have to use the accommodation was quite out of date yet from a health point of view good accommodation and bright surroundings were an even bigger contribution to recuperation than medicine. Taking the British seaside resorts generally the municipalities had spent more money and were superior to continental resorts in the arrangements made to cater for the pleasures of the people. But in accommodation and cuisine they lagged behind. Here was a great opportunity for municipal enterprise which would be called for since the extension of holidays over a lengthened season would cause the question of holiday centres or homes to be dealt with. These could not be erected in every health resort and if the millions were to be catered for some development must occur. In many industries it was impractical for the whole of the workers to take their holidays during the summer months and there were three other periods in the year which offered opportunity for catering if correctly handled—the late October Christmas and Easter. The maintenance of our health resorts would be largely dependent upon catering for the masses. Amongst the so-called

middle classes the idea was sometimes prevalent that the masses were just vulgar people, and so cheap and nasty accommodation was held to be good enough. But the popular standards were rising and time would show inadequate accommodation to be a very short-sighted policy. The food catering arrangements must be improved, people were used to better fare both in homes and restaurants and would not tolerate the stodgy, unappetising meals now set before them.

PRESERVATION OF THE COUNTRYSIDE

Mr Bevin spoke earnestly on the need to preserve the beauty of the countryside and coastline. "With the planning of the health resorts," he said, "and with improved architectural arrangements, due regard must be paid to the preservation of the coastline and countryside. So many beauty spots are spoiled by building speculators and others, whose sole idea is to reap in money in one form or another, and many local authorities also succumb to the desire to share in these developments. They do not fully realise their responsibilities and do not sufficiently exercise their powers of control. It must be remembered that a holiday is not only for enjoyment, to be effective it must also be cultural and health giving, and whilst you may bring prosperity to a few citizens by allowing development to go on in an haphazard manner, it is a short-sighted policy, and local authorities may find themselves saddled in a few years with burdens they should never have undertaken. Local authorities should exercise a strict control on the erection of buildings, whether for pleasure, hotel, or housing purposes, and keep them in conformity with the best architectural standards and the traditions of the place, plus the acceptance of modern ideas. Avenues, public gardens, and vistas should be kept spacious and ample space provided for recreation and games."

He went on to plead for more attention to the case of the children, the holiday, he pointed out, was not only for the man, it was for the woman also, and the family problem was a very serious one, so that facilities for the children to play in covered shelters during bad weather must be made. He commended the action of those local authorities who provided play centres on the beach, where the younger children could be looked after by trained nurses, allowing the mother to safely leave them for a few hours. He advocated holiday camps for children. The development of inland centres he commended as preventing the coastal resorts from being overcrowded and leading to a greater use being made of our spas and hydros. Here he pointed out that the preservation of the beauties of the surrounding countryside and its historical features would in the long run lead to and hold the business.

SUITABLE CONVALESCENT HOMES

Of the employment of health resorts to a much greater extent for the provision of convalescent treatment, Mr Bevin said that trade unions, friendly societies, approved and other societies had established buildings and homes under their own management, leading to a limited form of treatment and selection whilst, at the same time, literally thousands of pounds were being spent in convalescent benefit. The whole arrangement was uneconomic and the fullest benefit was not being derived. A co-ordinated scheme, in conjunction with our health resorts, for the municipalities and the societies to take a hand in really planning convalescent home treatment was wanted.

For suitable arrangements for curative treatment and a pleasant and restful vacation it would be a real boon. But convalescent homes must not be developed on institutional lines, they must be well appointed and free from too many restrictions, while the rooms should be large and airy, and cheerfully decorated. The home should stand in its own grounds. He added that although there were quite a number of convalescent homes throughout the country for men, the number provided for women was totally inadequate.

Mr Bevin concluded by asking for a Government commission to examine the problem of planning, equipment, and co-ordination of health resorts. He said: "I should like to see the Health Resorts Association urging the Government to set up a Royal Commission to examine the whole problem of planning, equipment, and co-ordination of health resorts. The work of this Royal Commission could proceed concurrently with that of the Holidays with Pay Committee, so that as a rapid expansion of holidays takes place we can get a great drive for public development and so cater for what will become a very important and vital industry to this country. The Royal Commission should not only take into account the planning of the existing health resorts, but also the problem of equipping such resorts. There may have a very great bearing upon certain spots in the Special Areas. The trade unions who have been working on this problem of holidays with pay and now have the task of trying to weave it into our industrial fabric have created as it were a raw material for the development of our health resorts far beyond the dreams of any of those who have been engaged in the business in the past."

THE HOLIDAY ATMOSPHERE

Dr Leonard P Lockhart, medical officer, Boots Pure Drug Co., Ltd., opened with the following wide definition of a health resort—"as I understand it is any place where a holiday can be spent." Hence it followed that it should meet the needs either of the person desiring a holiday or the person who is undergoing a routine treatment or resting for convalescence. He drew sound distinctions between the holiday maker and the patient, holding the holiday atmosphere to count most in most cases, and regretting that people were not sent away more often as a preventive. From personal experience he held that care should be taken to choose only the right place to be sent away, and he believed that in the convalescent home established by Messrs Boots at Skegness, money was spent on just those things. Holidays properly based on rates of pay would reduce the sick absentees. He pointed to the holidays being taken in family groups.

Mr J J Hewlett, representing the Hotels and Restaurants Association, disclosed some of the difficulties experienced by the hotel keeper, especially in places with short seasons, reminding the audience that hotels in Great Britain were handicapped, those on the Continent were not, by Government restrictions as well as by increasing rates and taxes.

The chair was taken at the afternoon session by Dr A D F Menzies, M O H for Skegness, and the session was devoted to the consideration of

Games, Sport, and Sea-bathing

The discussion was opened by Sir Kaye Le Fleming who said that he was not speaking as a member

the Government Advisory Council on Physical Education and was omitting from his remarks any consideration of nutrition although attention to nutrition was essential in any national attempt to raise physical standards. Pleasure, he said, could not be fully enjoyed without an education in its use; it was relaxation after work and the recreation of faculties for work. The British were a games-loving people and games were the specialised ends of physical education. Hence he would give a prominent place in the betterment of physical culture to such sports as tennis, swimming and skating which produced the balanced mind in the balanced body and would put in a plea for deck tennis, a game which it was easy to provide cheaply and which, as it took up little space, could be played indoors. All these sports he thought should be available for the mass of the workers so that they would have a chance to develop a sense of pleasure in the fitness of their bodies. With regard to bathing, he pointed out that there should be attached to every bathing centre a building—call it a gymnasium—not provided with any elaborate apparatus but where while exercises could be indulged in music and opportunities for refreshment were provided. In sea bathing much of the advantage was in the free exposure of the skin to the air and the reluctance of the male sex in this direction must be overcome; women had already got over it. The medical profession would have to give more serious study to the problems connected with physical education. And with regard to Skegness, he held the centre up to praise for the efforts that had been made to supply the necessary amenities adding that such efforts must be made more freely at seaside resorts.

Dr Cove Smith said the new Government movement in favour of physical education had come none too soon. The kind of individual we want to produce is the man and woman who is fit and feels fit. It was no use in so developing gymnastics that we produced people with the muscles of a Sandow who would die in the fifties with a fatty heart. The problem was to find out how our spare time of which there would be more for many people could be best employed. Modern machine repetition work had unbalanced the average worker while artificial inducements to exercise could not take the place of exercise in the open air. He dealt with the technical aspects of sea bathing, the appreciation of which was a comparatively new development. On the authority of Fanny Burney he said its popularity dated from the time when King George III took the sea at Weymouth followed by a bathing machine containing fiddlers who played "God Save the King."

Dame Louise Mellroy attributed great virtues in any gynaecological cases to seaside treatment. She who had been accustomed to much active life at school often fell into poor health when she was deprived of this and a visit to the seaside with active exercise and bathing was of great value. The same applied to many women in sedentary occupations rather than to those whose work was more active and sometimes really heavy. Middle-aged women with tendency to fat were greatly benefited. This country was behind the Continent in its health resorts but things being equal the avoidance of vice and tiring journeys with language and customs difficulties must be remembered. The native doctor would better treat the patient understanding her psychology and her home conditions than a foreigner could. It was a mistake to try to imitate con-

tinental cooking. She supported Mr Devin's plea for more convalescent homes.

Dr Menzies gave interesting figures about the meteorology of Skegness. There was a low rainfall and a high ultra violet rate. The place was specially good for post-operative cases and their best months were April, May and October. The tonic effect was greater then than in the summer months. They were proud of their children's day nursery with its trained nurses. They were fully alive to the importance of accommodation at hotels and had made a survey last year which would show good results. Their physical culture classes on the beach were very popular.

Dr H Sanguinetti (London) referred to Prof Keatner's recent work on the effects of sea air on children and said it pointed out one way in which doctors could take a greater part in the investigations needed to place this subject on a thoroughly scientific basis.

Mrs McCrae M.B. (London) from her experience of child welfare work strongly supported the claim of the wife of the industrial worker for the benefits of the seaside. Those she could not get unless she were at the same time relieved of much of her maternal worries.

Lieut Colonel W. Byam R.A.M.C. (ret.) chairman of the Medical Advisory Committee of the A.A.O.C. in moving a vote of thanks to the chairman said many sound ideas had been ventilated which would receive the attention of his committee.

HOSPITALITY

In the evening the members of the conference along with members of the local council and their ladies were entertained at a banquet at the County Hotel. Lord Meston proposed the toast of Skegness to which the chairman of the council replied giving many interesting details as to the growth and progress of the town. Councillor C. T. Jessup proposed the health of the association to which Dr Alfred Cox the secretary replied. The banquet which was enlivened by songs was a pleasant termination to a most successful conference.

MEDICINE AND THE LAW

Successful Claim against Widow of Doctor

THE litigation in *Connolly v. Rubra* forms a menacing precedent for the medical profession. A civil servant named Connolly dies of tuberculosis. His right of action does not die with him. His widow sues Dr Rubra, who attended the patient and alleges negligence in diagnosis and treatment. Dr Rubra is himself too ill to appear in court. He dies before the case is decided and damages to the amount of £3000 are awarded against his estate. The Court of Appeal declines to interfere.

Lord Justice Cresswell delivering the unanimous judgment of the court on April 7th emphasised the difficulty of the case. The original trial had taken place before Mr Justice Greaves Lord in circumstances of very great difficulty, inasmuch as the chief witness for the defence was not available. The trial judge had to decide whether he should accept the evidence of the plaintiff Mrs Connolly as to conversations she had with Dr Rubra. As the Court of Appeal observed Dr Rubra could not be called

to give his version of the facts, all that could be done was to criticise Mrs Connolly's evidence by reason of letters she had written and by reason of the absence of corroborative entries in Dr Rybra's books. Then there was another "very difficult question indeed." The plaintiff had to establish not only that Dr Rybra was negligent but also that his negligence was the cause of shortening the life of the patient. Lastly "the question of damages was also one of great difficulty." It was difficult for Mr Justice Greaves Lord to assess the amount, he must not fail to take into account the common risks of life to which all persons, even if healthy, are subject. It was also "very difficult for the Court of Appeal to interfere with his judgment, even though they might happen to think themselves that the award is rather on the generous side." The Court of Appeal was not entitled to assume that the trial judge failed to take into account the fact that Mr Connolly was "a frail and chesty patient." Unless the trial judge took into account matters which he ought not to have taken into account, or failed to take into account matters which he ought to have taken into account, the Court of Appeal would not upset his award. On the material questions of fact, said Lord Justice Greer, the trial judge, having to decide "between a living widow and a dead defendant," was entitled to make up his mind on the evidence given by the widow, provided that he took into consideration all the relevant criticisms which could be made with regard to her evidence.

It remains to summarise the observations of the Court of Appeal on the issue of professional negligence. Lord Justice Greer remarked that tuberculosis is one of many diseases with which a general practitioner commonly has to deal. If the doctor has any doubt whether or not there are signs of tuberculosis, it is his obvious duty to make further examination to resolve that doubt and to make it clear that nothing further can be done for the patient. A doctor who is not over confident of his own judgment will, when he finds himself in a difficulty, call in an expert and decide according to the expert's views. To enable the expert's opinion to be of value it is not enough to do what Dr Rybra did at a later period—namely, to take one specimen of the sputum and be content with that if the result is negative, he must take many specimens of the sputum and, in addition, he ought to have an X ray examination and to watch the patient to see whether he is progressing or going back as time goes on. "Dr Rybra unfortunately did none of those things." Ought he to have suspected tuberculosis when he diagnosed bronchitis? It was here that the widow's evidence was crucial. She gave evidence at the trial of interviews she had with Dr Rybra in December, 1930, she said she then told him of an effusion of blood from the patient's mouth in the summer holidays of 1929, of streaks of blood in the sputum towards the end of 1930, and of blood stains on his handkerchief. Believing the widow's evidence, the trial judge came to the conclusion that at the beginning of 1931, or at the end of 1930, Dr Rybra had shown such want of competent and ordinary skill and care as justified the claim for damages. There the case stands after an attentive hearing and a judicial review with which no doctor can quarrel. All must sympathise with Mrs Connolly and her children in their loss. Nobody disputes the bona fides of the evidence for the plaintiff. The state of the law nevertheless will cause the medical profession grave misgiving. Does it not often happen that the comments and statements made by a patient's relatives take on a quite different com-

plexion when one hears the version given by the doctor? Is it fair that the law should contemplate a decision upon the evidence of one side alone, and that a deceased doctor's estate should be liable for damages to the substantial amount of £5000 when, had the doctor's own evidence been available, the plaintiff might not have succeeded in establishing her case beyond doubt? The Court of Appeal saw the difficulties of the case. If these decisions between a living widow and a dead doctor have these heavy consequences, a disturbing distraction will embarrass the practitioner's mind.

The Doctor's Bad Debts

Though the Merseyside Medical Practitioners Association was formed to promote other and more general objects than the mere collection of bad debts, its efforts in the latter direction have attracted publicity and may be imitated elsewhere. One newspaper has stated that the Merseyside doctors estimated that outstanding accounts owing by local patients to medical men and dentists exceeded a total of £100,000. The defaults are represented as being on an unusually large scale. To prevent them from growing still larger, the members of the association undertake to furnish it periodically with lists of patients whose accounts are long overdue. The debtors are given a further chance to pay, if the chance is not taken the names are placed on a "defaulters' list," circulated confidentially to members. The doctor or dentist whose services are asked for by one of these defaulters is thus in a position to request payment in advance. This system simply applies to medical practice a method of protection well known elsewhere. Barristers' clerks have their own ways of knowing the firms of solicitors from whom no brief should be accepted without the accompanying fee. London shopkeepers are not entirely unarmed against customers who habitually open accounts without the means or intention to pay. Defaulters whom it is necessary to place on a "black list" are a nuisance, having exhausted their credit in one direction, they repeat the process in others. The plan adopted in the Merseyside district will protect newcomers from being imposed upon. Unless there is bad faith or breach of confidence in its operation, it is privileged and cannot give rise to libel actions. A doctor who of course attend a patient on the understanding that his service is gratuitous. In the absence of any such understanding, he is entitled to be reasonably remunerated for his professional work. He is certainly not obliged (unless there is some contractual obligation on his part) to attend any patient who chooses to send for him, nor is there anything to prevent him from stipulating that his services shall be paid for on a cash and not a credit basis.

A Mistake in Dispensing

At a Lancashire inquest on the death of a woman aged 60, during an operation shortly after the administration of a local anæsthetic, it appeared that the hospital dispenser had made a mistake. He had been asked to supply a one per cent solution of procaine hydrochloride, he had supplied not procaine but percarne hydrochloride. The coroner explained that, while procaine was a relatively harmless drug, percarne was deadly in anything but therapeutic doses. The patient had been in a serious condition without surgical operation her expectation of life was limited, but her death was due to the error. It was easy, observed the coroner, to be wise after the event. A verdict of "death by misadventure" was recorded.

ARTIFICIAL FEVER THERAPY (PYRETOTHERAPY)

FIRST INTERNATIONAL CONGRESS

On March 20th at the College of Physicians and Surgeons Columbia University New York City Dr Allen O Whipple, professor of surgery Columbia University welcomed the delegates to the first international congress of artificial fever therapy. Dr Pierre Abram, professor of pathology University of Paris replied and messages were then read from Prof A. d'Arsonval and from Prof. Julius Wagner Jauregg who were unable to be present. Prof d'Arsonval referred to his interest since 1890 in the physiological effects of currents of high frequency especially the painless rise in the body temperature which follows the use of the diathermic current. His friend Ferrié had actually used a medical type of apparatus for his first trials of wireless at the Eiffel Tower. Nowadays the position has been reversed and the wireless industry was providing short-wave apparatus for the physician. Prof Wagner Jauregg said that he first began injecting tuberculin to produce an artificial fever in cases of mental disease as early as 1891. Since 1900 he had been concerned primarily with general paralysis of the insane; some of his cases treated over 20 years ago with tuberculin were still in excellent health. He stressed the value of combined fever treatment and chemotherapy and concluded by saying that it should not be the aim of these combined methods to destroy the pathogenic organisms in the body but to improve the resistance of the organs and tissues against them in order that the infection would eventually die away.

Over 100 papers was submitted at the congress of which 56 were actually read. A few of them are summarised below.

PHYSIOLOGICAL EFFECTS OF FEVER TREATMENT

The first day of the congress was chiefly devoted to the physiology and pathology of artificial fever and J G Gibson, J Kopp and W A Evans (Harvard and Boston Mass.) submitted a paper on changes in blood volume during therapeutic fever. They found that the diminution in plasma volume was closely related to the intensity of sweating and weight loss. Intravenous administration of fluids soon restored the blood volume to normal. M Pijoan, Gibson and Kopp (Boston and Harvard University) had investigated the acid base balance during therapeutic fever and ascertained that if there was an excessive dehydration a pronounced alkalosis might occur. J D Hardy (New York) had studied the mechanism of heat loss from the human body and confirmed the view that heat loss is due to radiation, convection and vaporisation and depends largely on the environment. S L Warren (Rochester N Y) contributed an interesting paper on chloride balance in artificial fever. The maintenance of a proper fluid intake throughout the treatment was vital especially when long applications of from 10 to 24 hours were undertaken. Under suitable conditions the water loss by sweating might be compensated for by the ingestion of between 200-300 ccm of fluid per hour. Salt should only be administered when sweating diminished. A H Dowdy and F W Hartman (Detroit Michigan) contributed a paper on the preparation of patients for fever therapy with special reference to sedatives and fluid intake. They advised the use of a carbamide sedative in preference to any of the barbiturate acid group. It should be given first the night before

the treatment and the last dose on the following morning about one hour before treatment was begun. During the treatment ice drinks of 0.6 per cent saline and 3-0 per cent glucose were given orally.

RHEUMATIC FEVER, CARDITIS AND CHOREA

On the second day of the congress the use of artificial fever in a miscellaneous group of diseases was considered. E E Simmons and F Lowell Dunn (Omaha Nebraska) reported the treatment of 15 cases of acute rheumatic fever for periods varying from 8½ to 48 hours with temperatures of 103-106 F. Thirteen patients received complete relief from joint pain and swelling, two had relapses in from 2 weeks to 2 months and a third had a recurrence of chorea 21 months later. They believe that fever therapy reduces the symptomatic activity of the rheumatic fever and shortens the duration of the attack.

Three interesting communications on rheumatic carditis and chorea were made by S L Osborne, M L Blatt and C A Neumann (Chicago Illinois) by Lucy Porter Sutton and Katherine G Dodge (New York) and by C H Barnacle, J R Ewalt, and F G Ebaugh (Denver Colorado). Osborne and his collaborators had treated 25 children with chorea ranging in age between 4 and 16 years without encountering any difficulties. Nine cases were very severe, 6 moderately severe and 10 were considered mild. The average number of treatments given was slightly less than 4 and the average stay in hospital less than 16 days. The choreic movements ceased in 22 of the cases. Sutton and Dodge have been using fever therapy since 1930 at the Bellevue Hospital New York. They first employed injections of typhoid paratyphoid vaccine, subsequently they have treated 50 cases of chorea with a radiant energy cabinet the temperature maintained was between 105 and 106 F for from 4 to 5 hours. Most patients received one or two treatments, early cases however severe responded most quickly to fever therapy. Altogether 400 cases were treated. A preliminary analysis of 90 treated cases compared with 75 untreated revealed a definitely lower incidence of rheumatic manifestations including polyarthritis and carditis in the treated group. The authors expressed their conviction that fever was capable of cutting short an attack of chorea; that the presence of active carditis was not a contra indication and that fever therapy might in fact be a valuable therapeutic measure in rheumatic carditis. Barnacle and his colleagues had treated 45 cases of rheumatic carditis and chorea by physically produced fever. 14 were severe, 29 moderate and 2 mild. They preferred daily fever sessions of only 2½ hours duration at temperatures of 105-105.4 F. The average number of treatments given was 12.6, the average total duration of fever 32.9 hours and the average time under treatment 22 days. All the patients responded to fever therapy though there were three recurrences. Nineteen cases had rheumatic carditis and 12 of them showed a lasting improvement in cardiac function.

RHEUMATOID ARTHRITIS AND NEURITIS

The communication of R M Stecher and W M Solomon (Cleveland Ohio) concerned the treatment of acute non-specific infectious arthritis with artificial fever. Their 20 cases all suffered from an acute form of atrophic rheumatoid arthritis. Twelve patients received prompt relief and apparent cure while 8 were partially relieved. The course of the disease was favourably modified in every case. Temperatures of 106 F were maintained for from 2-2½ hours.

with an average of 7.3 hours in the cases showing complete recovery, and 5-30 hours with an average of 17 hours in the patients who eventually experienced only partial relief. Five out of 8 patients showing radiological evidence of joint damage were in the group which required longer treatment. The authors interpreted their results as an indication of the importance of prompt administration of fever treatment in order to avoid or minimise joint damage. A. E. Bennett and P. T. Cash (Omaha, Nebraska) dealt with the relief of neuritic pain by employing lower temperature levels and for from 2 to 4 hours' duration. Out of 20 cases of sciatic neuritis treated, 16 were completely relieved by fever therapy combined with epidural injections. Three out of 6 cases of brachial neuritis were permanently relieved by fever treatment alone. Four cases of toxic infectious polyneuritis obtained complete relief as did 3 cases of post herpetic neuralgia.

DISSEMINATED SCLEROSIS

K. M. Walthard (Geneva) and W. Kerr Russell (London) dealt chiefly with electropyrrexia in the treatment of disseminated sclerosis. In 4 of the latter's cases the gait deteriorated after treatment, in 5 there was no change, and in 6 there was improvement. Both authors stressed the difficulty of assessing the value of fever therapy in a disease characterised by natural remissions.

OPHTHALMOLOGY

J. S. McGavic (Cincinnati, Ohio) presented a preliminary report on 42 cases of various ocular diseases. He had found that in gonorrhoeal ophthalmia the fever therapy seemed to increase the amount of pus formed in the conjunctival sac following the first and second treatments, thereafter the discharge steadily diminished and smears became negative in a short time. Seven cases of syphilitic interstitial keratitis showed most impressive results. Patients were generally able to keep their eyes open after one or two treatments. A shorter course and fewer permanent synechiae were noted in cases of syphilitic irido-cyclitis. Treatment was given every other day for 5 hours, temperatures of 105°-107° F being employed.

THERMAL DEATH TIME OF THE MENINGOCOCCUS IN VITRO

Mary L. Moench (New York) had studied the heat sensitivity of 15 strains of meningococci in vitro at temperatures used in fever therapy. A semi-solid veal infusion agar was used for the cultures. At temperatures ranging from 40°-42° C all strains except one showed reduction or cessation of growth within 5-7 hours, the maximum reduction occurring at 41° C and over. Dr. Moench considered fever therapy to be worth trying as an adjunct to other treatment in carefully selected cases of meningococcal infection where serum therapy had failed or could not be used.

SYPHILIS

On March 31st six papers were devoted to syphilis. A. Bessemans (Ghent) outlined his experiments with hyperpyrexia. He found that the treponemata of both rabbits and man rapidly became immobile and disappeared after a temperature of 42° C for 1 hour or 40° C for 2 hours. L. E. Hinsie and J. R. Blalock (New York) gave a survey of 12 years' work in a paper on serology in general paralysis of the insane. 326 patients were treated by one of four different methods of treatment: malaria, tryparsamide, and electropyrrexia with and without

tryparsamide. The serological findings were analysed at yearly intervals over a 12 year period. The most favourable clinical and serological results were observed in those patients who received fever therapy followed by chemotherapy. For purposes of prognosis, the authors advocated serological examination three or four years after treatment had been started. F. R. Menagh (Detroit, Michigan) had treated 19 syphilitic cases with hyperpyrexia combined with chemotherapy, more than a half showed improvement, and nearly one half of these had been treated previously for an average of five years by chemical means without success. Of the 45 cases of general paralysis of the insane and 27 of tabes dorsalis the best results were obtained in the early cases with minimal tissue damage. Perforating ulcers and Charcot's joints were favourably influenced as were the 10 cases of optic atrophy. Ten cases of asymptomatic neurosyphilis and meningovascular syphilis did exceptionally well. W. M. Simpson and H. W. Kendall (Dayton, Ohio) had formed the opinion from a study of 34 cases of early syphilis under combined therapy that artificial fever fortifies and intensifies the curative action of chemotherapeutic agents. Fever therapy alone or chemotherapy alone was inadequate in a high proportion of control cases. C. A. Neymann (Chicago, Illinois) claimed that electropyrrexia had increased the percentage of improvement in general paralysis of the insane to 21 per cent, and that the combined fever treatment and chemotherapy cured most cases of early syphilis promptly and permanently in one or two months.

GONOCOCCAL INFECTIONS

On March 31st C. M. Carpenter and Ruth A. Bock (Rochester, N.Y.) dealt with the thermal death time of 250 strains of gonococcus at a temperature of 41.5° C (106.7° F). The heat resistance of the organisms varied from 6-34 hours, the mean being 16.1 hours. The figures for strains isolated from patients and their consorts showed a close agreement. S. L. Warren (Rochester, N.Y.) found that 87 per cent of 100 consecutive cases which were given fever treatment for a period equal to the thermal death time of the isolated organism at 41.5° C were cured bacteriologically and clinically by the end of the treatment. He considered that the thermal death time test was a practical guide in determining the length of the fever treatment necessary for each individual patient. W. Bierman and E. A. Horowitz (New York) described the method by which they had treated 121 cases in the last six years, with success in 113. They first raised the systemic temperature by physical means and then applied additional heat locally to the pelvic organs, generally with the diathermic current, for a period of 7 hours. The systemic temperature was kept between 105.5° and 106.5° F for 12 hours, during 7-8 hours of which the pelvic temperature was maintained at 109°-110° F. One to three treatments were given, but the average was only 1.4. One third of the patients had epididymitis and the pain generally disappeared during the first treatment. F. A. Krusen, L. G. Stahlke and L. M. Randall (Mayo Clinic, Rochester) also contributed a paper on combined systemic and local heating in gonococcal infections. 361 patients were given 1698 artificial fever treatments at an average temperature of 106.7° F. The average number of treatments per patient was five. Forty patients who proved refractory to systemic fever alone were given additional local heat, and 80.5 per cent then developed negative cultures. Ten hour sessions of fever were given, 92.5 per cent of all the patients who completed

their treatment had negative cultures. They believed that often a single long session of fever combined where suitable with additional local heat offered the most satisfactory method of treating gonococcal urethritis, cervicitis and pelvic inflammatory infection. A. E. Belt and A. W. Folkenberg (Los Angeles California) found that 92.3 per cent of their cases were consistently free from organisms following one 10 hour session of fever.

E. H. Parsons, P. N. Bowman and D. E. Plummer (Denver Colorado) compared the results of fever treatment in male patients with those obtained by injections, irrigations and massage. They stated that the number of cures in the fever treated group of acute prostatitis and complications was significantly greater than in the control group and that the fever cases only required a quarter of the time needed for the controls. Acute prostatitis invariably disappeared after one fever treatment. J. A. Troutman, H. V. Stroupe and D. J. Devlin (New Orleans Louisiana) described their experiences in the treatment of 278 patients with gonorrhoea; they found that fever sessions of five hours gave early and complete relief in cases of acute epididymitis, acute arthritis, and acute prostatitis. T. G. Schnabel and F. Fetter (Philadelphia Pennsylvania) had treated 130 cases of gonococcal infection with an average of 4½ treatments. Thirteen out of 15 cases of gonorrhoeal vulvo vaginitis were cured. Out of 93 patients with gonococcal arthritis 54 were cured and 30 improved. Comparing the arthritis cases treated by fever with the controls they found that fever therapy appreciably shortens the period of hospitalisation and improves the prognosis. H. A. Freund and W. L. Anderson (Detroit Michigan) described the recovery of a case of gonorrhoeal endocarditis treated by artificial hyperpyrexia and O. G. Hazel and W. B. Snow (New York) a case of gonococcal septicaemia with purpura and arthritis which was successfully treated in this way.

SOCIAL EVENTS

There was an excellent exhibition at the Waldorf Astoria Hotel New York at which 11 firms demonstrated their apparatus. On two evenings films were shown dealing with the various methods of inducing hyperpyrexia and the results obtained. On March 31st New York physicians entertained the foreign guests to luncheon. The congress banquet was held on March 30th when the French delegation conferred the Legion of Honour on W. R. Whitney, C. F. Kettinger, W. M. Simpson and W. Bierman the indefatigable secretary of this successful congress.

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

EDINBURGH ROYAL INFIRMARY

THE managers of the Royal Infirmary have issued an appeal for £200,000 to complete the cost of the many extensions that they are making. An interesting development is the return of the Maternity Hospital to the Royal Infirmary for in the year 1757 the first attempt to provide institutional facilities for maternity cases was in an attic in the old Infirmary in Infirmary-street. Forty years later a maternity hospital was established independently on the site of what is now the University Union and in 1870 the present Edinburgh Royal Maternity and Simpson's Memorial Hospital was opened in Lauriston place. Since its opening the number of infants born within

the hospital has risen from 150 in the first year to 2500 during 1936. In addition 950 cases were attended to in their own homes in the district. No fewer than 40 per cent of the total births in Edinburgh occurred under the care of this institution. It is interesting therefore to note that the Maternity Hospital is again to come under the wing of the Royal Infirmary and the new Maternity Pavilion which is to have 130 beds should be ready for occupation in 1938. An advantage of this new development is that the Maternity Pavilion will be adjacent to the present gynaecological wards.

A new nurses home providing for additional accommodation for 300 nurses is also nearing completion. The radiological department has been equipped with the most modern apparatus and new departments for orthopedics and neurosurgery are being constructed. A new Dermatological Pavilion in which the venereal diseases department is also situated has recently been opened. In view of these extensive recent developments it is not surprising that the managers have some anxiety for the future financial position of the institution.

UNIVERSITY HALL, EDINBURGH

To celebrate the jubilee of the opening of University Hall a dinner is to be held in the North British Station Hotel on Saturday May 20th. A large number of old residents of the various houses have intimated their desire to attend and it is hoped that any who have not already done so and who wish to come will write without delay to Sir Thomas Whitson, 21 Rutland-street Edinburgh.

MATERNITY AND CHILD WELFARE IN ROMANIA

THERE are at present 4000 qualified midwives in Rumania far too few for the country's needs. Unqualified women who are not properly trained have therefore to be employed in many districts and since there are not enough doctors available for consultation in difficult cases the mothers are not very well served. Dispensaries dealing specially with the protection of mothers and children number 107; most of these are managed by private charitable organisations with government subsidies. The conditions for the conduct of labour are fairly primitive in the villages and the risk of infection is great. Confinements are still often conducted in a bed of straw and in some remote parts of the kingdom there are no professional midwives of any kind handy and the labour is conducted by a member of the family. For complicated cases there are 22 maternity homes in the country in connexion with hospitals or university clinics and 20 smaller ones are maintained by private charity. The Minister of Public Health has declared his intention in 1937 to establish maternity homes in every county hospital.

The infant mortality rate is very high in Rumania. According to Prof. Meinescu who is director of the Institute of Hygiene and Public Health the rate for the last five years (1931 to 1935) has varied between 174 and 192 per 1000 live birth. This high rate is attributed to the ignorance of the mothers about the hygiene feeding and clothing of infants. The care of infants is now to be taught to senior girls at secondary schools and to university students. In the villages also nurses will lecture to wives and

to untrained midwives Travelling clinics and dispensaries already visit some villages twice a month and it is hoped to extend this service to all counties in the kingdom

INTERNATIONAL CONGRESS OF MILITARY MEDICINE AND PHARMACY

The ninth international congress of military medicine and pharmacy will be held in Bucharest from June 2nd to 10th The aims of the congress, which has been held in previous years at Brussels, Rome, Warsaw, Paris, London, Hague, and Madrid, are (1) to study practical methods of handling and treating wounded and sick soldiers, (2) to maintain good relations between the sanitary officers of various nations, and (3) to arrive at certain international conventions designed to lessen the horrors of warfare The committee entrusted with the organisation of the congress consists of civil and military medical members, and is presided over by Surgeon General Dr Ilescu The scientific programme includes the discussion of six problems, the opening addresses at each discussion will be given by representatives of different nations The organisation of sanitary services in operation on the field and at sea will be described by members from England and the United States Germany and Yugoslavia supply the principal speakers on the transport, hospitalisation, and treatment of gassed patients, and Swiss and Japanese delegates will discuss the use of the different colorimetric analyses in the laboratory Dentistry, with especial reference to edentulous soldiers, is the subject allocated to Greece

and Holland, while France and Turkey will supply material for a comparative study of the alimentary of sick and wounded soldiers in time of war and peace The organisation and functions of the surgical service attached to mechanised units will also be discussed

The reports will be published in English, French, German, Italian, and Spanish Membership of the congress is open to doctors, dentists, veterinary surgeons, pharmacists, or administrative officers attached to military, naval, or air force services The registration fee is 1000 lei (about 30 shillings) which entitles members to receive official publications and to join in festivities arranged in connexion with the congress Further information can be had from the secretariat general, Institutul Sanitar, Militar, Bucuresti, II, Rumania

TREATMENT OF ACUTE SORE THROAT WITH BISMUTH

At a recent medical congress Dr Mayersohn reported experiences with the administration of bismuth in acute sore throat He was induced to give a trial to this practice by favourable reports published from the university clinic of Rio de Janeiro According to the reports the symptoms of any kind of acute or specific sore throat were greatly reduced within 5-6 hours by the application of one or at most two intramuscular injections of bismuth Dr Mayersohn had applied this method in his hospital and private practice to 1180 cases with only 48 failures A bismuth preparation containing 0.06 to 0.08 grams of bismuth in one dose is suitable for trial

GRAINS AND SCRUPLES

FROM A TADDYGADDY

IV

"That it may please thee to shew thy pity upon all prisoners and captives"

THE men who compiled the Litany had big hearts and wide understanding They thought of everybody Perhaps there was more time for thinking in their day, when everybody was not in such a desperate hurry to get somewhere, or do something else Not so long ago a wise bishop suggested, in the course of a discussion on the alleged conflict between Science and Religion, that what men should do was sit back and consider the multitude of facts and alleged facts accumulating all the time, and do a bit of sorting In other words, he asked men to sit down and think

* * *

If they would do that it might be that they would turn their minds to the problem of prisoners and captives to the tragic fate of those who have been deprived of liberty, sometimes for years I am referring now to those unfortunates who, for this reason or that, have been certified "M.D.," mentally deficient, and confined in a colony for mental defectives What proportion of those confined and shut up I have wondered often, really are so mentally afflicted that they need segregation for their own safety or the safety of others? I have made attempts from time to time to do a little towards finding out, and more than once I have been startled I was assured not so very long ago that, in the opinion of an official person wielding considerable power, any

young woman, if poor, who produced more than an illegitimate child should be regarded as morally defective and, if possible, certified and shut up I am assured, quite recently, by an official holding a position of the first importance and power that in his opinion a single act of childish sexuality was, in itself, a sufficient reason for keeping a boy of nineteen in a colony for an indeterminate period That boy had been certified "feeble minded" in spite of the fact that for two years he had kept his job to the complete satisfaction of his employers, and had earned good money For two years, also, he had served satisfactorily in the Territorials

* * *

I have an uneasy feeling that there are powerful people, officials with official mentality, who can do nothing harmful in depriving young people of liberty solely because the young people do not conform to their, often quite arbitrary, standards of intelligence and conduct Intelligence tests are in favour of day people with card index minds I submit they may be, and sometimes are, exceedingly dangerous 5 years ago I walked into a magistrates' ante room and fired off a salvo of mental intelligence tests at two magistrates sitting there I had no difficulty in demonstrating to them that they were, according to accepted standards, both mentally deficient One of them was the magistrate who did all the certifying after medical examination, of the alleged M.D.s of that district They were annoyed The certifying one was quite cross about it, particularly when I urged him to consider the moral of the experience

had tried upon him. It was no use. He was an ex-schoolmaster, convinced that he had nothing to learn from anybody.

Do you remember the little cages each with its little bird that used to hang in clusters outside the shops and houses in Seven Dials? It was a depressing spectacle. Unfortunately, very few of us ever go and look at the captives in our mental homes or colonies for mental defectives. Once a young person is immured there he seems to be forgotten. He is visited officially by officials and semi-official visitors but by how many non-official persons? For that matter what do most of us know about the inside of any State, or municipal, institution? I was struck by the speedy return home from a municipal tuberculosis sanatorium of people who had gone there filled with hope. I made inquiries. One reply was suggestive: 'It's all so dull. There's nothing to do and nobody seems to care. There's a billiard table we can use in the evenings but the cues have no tips. There are cards in the huts but there's never a complete pack. I went and had a look for myself. The complaint was well founded. There was nobody who seemed to care: nobody to whom a patient could pour out his griefs little or big.'

There has been much discussion concerning voluntary versus municipal in the hospital world. So far as the purely business, the financial, aspect is concerned the municipal advocates have it every time. But so far as the human aspect is concerned the voluntary advocates win hands down. In voluntary institutions the inmates are not at the mercy of officials: in State or municipal institutions they are. That I submit is where a great deal of trouble lies. We members of the visiting staff of a voluntary hospital go in and wander about as we please talking to the patients, listening to their grouses. We sense the spirit of the place. State and municipal institutions however materialistically efficient lack that human element. In mental homes in colonies for mental defectives it seems to be completely non-existent. The inmates are cut off from contact with the outside world.

Is this all unduly serious for the Grains and Scruples page? I hope not. I am writing as a Taddygaddy a practising G.P. and I prefer to write about subjects that concern my immediate job. The unhappiness—particularly the preventable unhappiness—of other people especially young people is very much the concern of all of us. I feel in my bones that all is very much not well in the officially run, officially controlled institutions in which young people are kept captive. I am impelled to say that not merely because of my own observations, but because of things said to me by other people of good will notably a Roman Catholic priest of vast experience and the widest possible sympathies who told me so lately as to day of his acute apprehension and unhappiness concerning the fate of young persons condemned to what amounts in practice to an indeterminate sentence of deprivation of liberty.

If I seem to finish up my series on a somewhat bitter note it is because circumstances quite recently have caused me to feel bitter—on behalf of young people who are defenceless when confronted by the stern arm of Authority. We doctors who practise in and about back streets see much of the seamy side of life. We do what we can to mitigate it but that

is not very much. We can, however, give some sort of publicity to abuses when we meet them—if we will. That is why I have made this the concluding article. It is very far from complete for reasons which I need not specify. I have been dealing recently direct with Authority which has been entirely kind and considerate and courteous but so far I have not succeeded in persuading it to do anything. The unfortunate confined weak ones for whom I have been contending are still confined. So far as I can see they are likely to go on being confined.

What is the matter with Authority? What is wrong with the Official Person? There is, hung up in one of our cathedrals—I think it is Chester—an old poem whose message seems somehow not to have reached the world of officialdom. This is how it finishes:

Give me a sense of humour Lord
Give me the grace to see a joke
To get some happiness from life
And pass it on to other folk.

That message, I submit, if accepted and acted upon by us all would serve as solvent for many of the anomalies and acts of seeming injustice that perplex us.

May I turn in conclusion to another old world writer? I open his book at random, and this is what I light upon:

Mercy will soon pardon the meanest

That is a sentiment which should appeal to us who as poor men's doctors see so much know so much of conditions under which the meanest is not pardoned. Rather is he not infrequently shut away from the sight of men and only too often forgotten.

*** This concludes the four articles by Taddygaddy. Next month a Medical Economist will be responsible for these columns.—ED.]

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED
APRIL 10TH 1937

Notifications.—The following cases of infectious disease were notified during the week: Small pox 0; scarlet fever 1013; diphtheria 912; enteric fever 21; pneumonia (primary or influenza) 1101; puerperal fever 53; puerperal pyrexia 124; cerebro-spinal fever 30; acute poliomyelitis 11; acute polio-encephalitis 0; encephalitis lethargica 4; dysentery 18; ophthalmia neonatorum, 6. No case of cholera plague or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on April 10th was 3263 which included: Scarlet fever 519; diphtheria, 91; measles 40; whooping-cough 528; puerperal fever, 14 mothers (plus 11 babies); encephalitis lethargica, 233; poliomyelitis, 1. At St. Margaret's Hospital there were 19 babies (plus 6 mothers) with ophthalmia neonatorum.

Deaths.—In 127 great towns including London there was no death from small pox, 2 (0) from enteric fever, 11 (0) from measles, 0 (0) from scarlet fever, 32 (11) from whooping-cough, 41 (0) from diphtheria, 51 (15) from diarrhoea and enteritis under two years and 112 (10) from influenza. The figures in parentheses are those for London itself.

There were 4 deaths from enteric fever and 4 from diphtheria at Liverpool. Four deaths from measles were reported from Birmingham. Leeds and Middlesbrough each reported 3 fatal cases of whooping-cough.

The number of stillbirths notified during the week was 278 (corresponding to a rate of 31 per 1000 total births) including 34 in London.

PUBLIC HEALTH

Mental Health in Scotland

THE number of insane persons under the General Board of Control for Scotland in 1936¹ was less by 103 than in the year before. The decrease is not high in comparison with the total figure, which is just under 20,000, but it is reassuring to see that the number has not risen. There is a corresponding small decrease in the average annual admissions to institutions over the last five years. More and more patients are now being treated in the observation wards of poor law hospitals and in nursing homes, and fewer patients with a good expectation of recovery are being sent to asylums. Nevertheless, the asylum recovery rate remains as high as one third of the number admitted. The Mental Treatment Act, 1930, does not apply to Scotland—a fact of which one is reminded by the use throughout the report of the traditional terms “asylum,” “lunatic,” and “pauper”—but the Scots law allows voluntary patients to be received into asylums, and the increase in the numbers of voluntary admissions has been steady and continuous. The Board, however, report a steady accumulation of certified patients in institutions. The result of this accumulation is, they say, that all asylums are now more or less fully occupied and most of them are overcrowded. They suggest that the problem could be partly met by providing more observation wards and establishing out-patient clinics to encourage early treatment still further. The mere substitution of “mental hospital” for “asylum” will not, they think, entirely remove the inherent public dislike of institutions, and although the problem of detention has to be met they regard as much more urgent the problem of providing treatment at a stage when it is likely to be effective. They therefore strongly recommend to the directors of all Royal Asylums the establishment of clinics entirely apart from the mental hospital but under the administration of its expert staff. Similar clinics, both resident and out-patient, should, they say, be provided by local authorities in association with general hospitals and supervised by expert psychiatrists. Municipal authorities would probably need an Act of Parliament to permit them to set up these new services.

SHORTAGE OF STAFF

Scotland appears to suffer from shortage of staff in much the same way as this country, with the result that research and treatment are badly hindered. The service therefore does not attract as many first class men as it should, for the medical officer is overburdened with routine duties and advancement is slow and uncertain. A familiar vicious circle is thus created. A further burden is thrown on the medical staff by the absence, in many asylums, of lay officers such as stewards, farm managers, and dispensers. Not only, therefore, are the medical staff unable to devote sufficient time to treatment within the asylum, but they are unable (except in the large towns) to carry out extra institutional services in out-patient clinics and observation wards. On the other hand, the possibilities of guardianship are used fairly fully and the system is working well. The reports of some of the deputy commissioners throw an interesting light on its everyday realities.

Compulsory Pasteurisation of Milk

The logic of facts is directing more and more attention to the need to extend control over the safety of the milk supply of this country. For a number of years milk has been a much discussed article, but along two distinct though really interrelated lines. The attention now paid to problems of nutrition always leads to renewed emphasis upon the nutritive value of milk and the need for more of it being consumed. For a great many years the medical profession has emphasised that the milk consumed in large areas of the country is a definite and important factor in the spread of disease, and while equally emphatic as to the nutritive value of milk submits that it must be safe milk. The existing legal powers are demonstrably inadequate to solve the problem. The very widespread outbreak of enteric fever last year in certain seaside towns, spread by raw milk, and other recent outbreaks also spread by raw milk in Doncaster and elsewhere show how necessary and urgent is the problem of adequate control. While the risk of the spread of bovine tuberculosis can be removed by the elimination of tuberculosis from our dairy herds experience shows that this is not yet a practical measure and at the best must take a great many years to be made effective. The only satisfactory way to render milk safe and yet not damage its nutritive properties is by its efficient pasteurisation. Local authorities anxious to protect the people for whose health they are responsible are now perceiving the desirability of enforcing adequate treatment of milk. Two of them—Glasgow and Poole—have now under consideration a scheme of obtaining powers to ensure efficient pasteurisation of the raw milk distributed within their areas, and in support of this movement their medical officers of health have issued illuminating and interesting reports. That coming from the public health department of the corporation of Glasgow² reviews the problem as it affects Glasgow. The daily liquid milk supply of Glasgow is said to be about 71,543 gallons. Of this 44.8 per cent is pasteurised under licence, 39.5 per cent is given uncontrolled pasteurisation (including a very little scalded or sterilised), 3.5 per cent is raw tuberculin tested milk while 12.2 per cent is consumed raw and ungraded. There are only 50 byres in the city, so practically all the milk comes from outside districts. Nearly all the milk (93 per cent) is distributed through the premises of wholesale or large retail tradesmen, and only about 2 per cent is sold by the producer distributor. On the cleanliness side the figures show that more than half of the raw milk sampled does not conform to a reasonable standard. Other facts in the report show that Glasgow is very well placed for an experiment in compulsory pasteurisation and a scheme could be operated with comparatively little difficulty. Since such a large proportion of the city milk supply passes through milk depôts, most of which are of considerable size, there are no inherent difficulties in requiring this milk to be efficiently pasteurised. The milk is heated by uncontrolled pasteurisation in practically all in such depôts and the plants could readily be converted into pasteurisation plants of approved type and working. The report also contains a fact-

¹ Twenty-third Annual Report of the General Board of Control for Scotland (Cmd. 5408). Edinburgh: H.M. Stationery Office, 1937. Pp. 45. 1s. 3d.

² A Review of the Milk Supply of Glasgow in relation to Pasteurisation. By I. McCracken, M.B., D.P.H., and A. Stewart.

detailed review of the facts as to diseases spread from contaminated milk and notes on pasteurisation methods and practice

In Poole compulsory pasteurisation powers are being asked for in a parliamentary Bill in the form of power to make by laws

The Corporation may make byelaws for prohibiting regulating or controlling the sale or supply or the exposure or keeping for sale or supply within the borough for human consumption or for use in the manufacture of products for human consumption of milk which has not been pasteurised and at all times securely protected against contamination in such manner as may be prescribed by the byelaws

Pasteurisation is defined in the same terms as in the Milk (Special Designations) Order 1930. The medical officer of health for Poole (Dr R. J. M. Horne) has also submitted a valuable report dealing

with the dangers of raw milk and the need for these powers to require pasteurisation. Such reports though they supply useful argument cannot in the space available review more than a small part of the overwhelming evidence available in favour of compulsory pasteurisation. Those interested will, however be able to consult many other sources including the authoritative report by the Committee on Cattle Diseases to the Economic Advisory Council and the several reports of the People's League of Health.

We welcome the efforts of the corporations of Glasgow and of Poole to carry out one of their primary functions the protection of their inhabitants from the risk of milk-spread infectious disease by seeking to secure powers requiring the efficient pasteurisation of the raw milk consumed within their areas.

OBITUARY

JOSEPH FAYRER Bt, C.B.E., M.D. F.R.C.S. Edin.

We regret to record the death of Lieut. Colonel Sir Joseph Fayrer which occurred in Gullane East Lothian on April 13th in his 79th year. He was the second son of Surgeon General Sir Joseph Fayrer, famous for his gallant service at the siege of Lucknow during the Indian Mutiny and author of the *Thakutphida of India*.

Joseph Fayrer was born in 1859 and educated at Rugby Trinity College Cambridge and St. George's Hospital where he commenced his medical studies. Later he went to the University of Edinburgh where he took the diploma of F.R.C.S. Edin. later graduating at St. Andrews as M.D. He went immediately into the R.A.M.C. entering in 1886 at the top of the list. He was stationed for a year at Edinburgh Castle and was then dispatched on foreign service, where following in the footsteps of his father he spent most of his time in India. His career there was that of an energetic officer and he became specially marked out for his administrative work in hospitals. On returning to England in 1894 he was appointed medical officer of the Royal Horse Guards a post which he held for three years. He then went to India for further service until 1903 when he returned to England as staff adviser and secretary to the P.M.O. of the London Military District. At the expiration of that post he became superintendent of the Duke of York's Military School then situated in Chelsea where his energetic and sympathetic activities gained him large credit. He held this post for five years when he went to China in charge of the Military Hospital Hong Kong. In 1907 he succeeded to the baronetcy and while in Hong Kong was appointed in 1911 superintendent of the Edinburgh Royal Infirmary a position which he held for 13 years a period covering the years of the war. During the war he was in command of the 2nd Scotch General Hospital Craigleith and was made a C.B.E. in 1919. He retired from the superintendency of the infirmary in 1923 on the age limit. Both at the infirmary and at Craigleith his charm of manner and capacity for friendship assisted him in a marked way in the discharge of his duties.

Sir Joseph Fayrer married Ella daughter of the late Colonel W. J. Mayhew and leaves a widow, two daughters and one son who succeeds to the title.

A lifelong friend writes: At Cambridge and at St. George's Hospital Fayrer collected friends and throughout a long and varied career he showed the

same power. He had an alert attractive appearance and a sympathetic manner the outcome not of a desire to please but of a willingness to be pleased. He was a game player and a sportsman when official duties gave him the opportunity. He always saw the best side of the other man and had a gift for friendship. His death will be regretted by very many.

ROBERT LYALL GUTHRIE, O.B.E. M.D. Edin.

Dr Robert Guthrie whose death occurred on April 13th was the son of the late James Guthrie Hope Park Broughty Ferry Forfarshire. He was qualified alike as doctor and barrister commencing with the medical profession a connexion on which he always insisted. He graduated in medicine at the University of Edinburgh as M.D. C.M. in 1892 and held several resident appointments. For a time he practised at Bethnal Green when he also studied law. He acted as deputy coroner to the late Dr. Wynn Westcott and in 1897 was called to the Bar at the Middle Temple. In 1903 he was deputy coroner for the Eastern District of the County of London the post which he was holding in 1914. During the war he was at the outbreak medical officer to the 7th London R.F.A. later he was commandant of the Fulham Military Hospital with the rank of brevet major and was then promoted lieutenant colonel and took command of the Belmont Prisoners of War Hospital. He was a successful administrator in all those posts and for his services received the O.B.E. After the war he resumed his duties as coroner and in 1921 became coroner to the Eastern District. As a coroner he was primarily a doctor and refused to be diverted from what he held to be his basic duty—namely to find accurately the cause of death. In his court one would frequently find cases being decided plainly and simply which were likely to have had far reaching consequences—cases of accidents at work in docks or factories where several parties were interested in the issues. In these circumstances his kindly attitude and his common sense decisions received wide appreciation—appreciation which led on one public occasion to Mr. George Lansbury referring to him as the ideal coroner. He was in addition a capable man of affairs was honorary treasurer of the London and Counties Medical Protection Society and medical adviser to the Law Union and Rock Insurance Company.

Dr Temple Clark writes: "Legal medicine has suffered a distinct loss in the passing of J. I. Guthrie."

There were united in him all the qualities which go to make the best type of coroner—an up to date knowledge of medicine, a sound grounding and grip of the law, and much shrewdness and tact in the conduct of an inquiry. Those who are not in close contact with coroners and their work can have no idea of the services rendered to the public by such men as Guthrie. Of failing health for some years past, one could not but admire the way he stuck grimly to his task to the end."

Dr Guthrie died at his home at Wimbledon in his 70th year.

CHARLES COLES, M.D. Lond

Dr Charles Coles died suddenly on April 15th at his home in St Margaret's road, Oxford, where he had lived in retirement for some years. He was the son of the late Mr J Coles of Uxbridge, and was educated at St Bartholomew's Hospital, where he distinguished himself as an athlete in football, cricket, and tennis. He filled there the offices of house physician and house surgeon, and was also house physician at the Brompton Hospital for Consumption. He held the Brackenbury scholarship at St Bartholomew's and graduated as M.B. Lond. in 1890. Two years later he took the M.D. degree, securing the gold medal, and later was awarded the gold medal when taking the M.D. degree in State medicine. For a short time he was in practice in Leicester but gave this up owing to temporary ill health, and entering the public health service was in 1899 appointed medical officer for the combined districts of Leicester shire and Rutland. In 1901 he was appointed medical officer for the Oxfordshire united sanitary districts and in 1911 county and school medical officer to the Oxfordshire county council. His work for the county council was never spectacular but was always sound. It was not an easy task for the demand for an increase in the scope of the public health services was difficult to satisfy from the resources of an agricultural area. In these matters he was always loyal to the county council while yet retaining the respect and regard of the medical profession.

Coles's leisure time was spent in gardening and in the study of the natural history of the country side, especially butterflies and birds. He had the "gardener's thumb," and plants flourished under his care, even in the poor soil of a north Oxford garden he made roses bloom to perfection. He would spend the greater part of the day after retirement in his garden, and his great delight was to point out to the occasional visitor the points of growth and development of the different varieties and how he had been able to produce the result. He had a small greenhouse and grew roses in pots for early blooms. He had also an extensive knowledge of field botany.

He was of a retiring habit and did not make many friends, but his friendship when given was real and lasting. He leaves a widow, a son, and a daughter.

JOHN TAYLOR, M.D., Ch.M. St. And

Much regret was felt at the announcement of the death on April 14th, at the age of 44, of Mr John Taylor, hon. surgeon in charge of the Orthopaedic Department, Dundee Royal Infirmary.

Mr Taylor, who had been in poor health for about two years, had been unable to carry on his practice for some months. He graduated M.B. Ch.B. in St Andrews University in July, 1914, and a month later went out to France before the majority of the Expeditionary Force had left this country. He was,

however, early invalided home and in 1916 appointed resident surgical officer in the Dues War Hospital. In 1917 he proceeded to the M.D. degree and again went abroad on service, on this occasion to Mesopotamia as surgical specialist. From this field of operation he was invalided, but later became senior medical officer in Bihar and Orissa. At the war he continued in association with the Territorial Force, in which he ultimately held the rank of colonel and was A.D.M.S. to the 51st (Highland) Division. He was specialist in tropical diseases in the Ministry of Pensions and surgeon to the Dundee orthopaedic annexe. When he rejoined the medical school he acted successively as assistant to a professor of pathology and lecturer in regional anatomy at University College, Dundee. He was appointed surgical tutor at Dundee Royal Infirmary in 1920, later assistant surgeon, and finally orthopaedic surgeon. On his resignation in 1935 on account of ill health he was appointed honorary consultant surgeon. He was a fellow of the Association of Surgeons, member of the Anatomical Society, and an associate member of the Orthopaedic Society of Great Britain. He gave much time to research and for ten years with Prof Weymouth Reid and Dr Shiven, carried on investigations into the function of the pancreas.

His death is regretted among all classes of the community in Dundee, he was known as an able surgeon and a generous hearted and kind friend.

DAVID SMART, M.B., Ch.M. Edin

Dr David Smart, who died suddenly on April 1st at Bootle, was medical referee to the Shipping Federation. A Scotsman born at Meigle, Perthshire, he was educated at Dundee High School and the University of Edinburgh, where he graduated as M.B., Ch.M., obtaining at the same time the Buchanan fellowship. He was for a period resident in charge of the gynaecological wards at the Edinburgh Post Infirmary and then went to Liverpool on appointment to the Smithdown Road Institution, becoming assistant surgeon to the Liverpool Hospital for Women and the Toxteth Poor Law Hospital. At the Liverpool Hospital for Women he met his wife, Dr Blanche Z. Smart, who was also a medical officer at the institution, and for many years they were in general practice in partnership. The war forced Dr David Smart well equipped. He had already given service to the old volunteers and when he came to Liverpool continued his association with the territorial army by joining the 6th Liverpool Rifles. He was associated with Dr Graham Martin in raising the Liverpool bearer company, whose members were later transferred to the 1st and 2nd Lancashire Field Ambulances. During the war he was Assistant Director of Medical Services to the 57th and 73rd Divisions, and retired with the rank of Col. A.M.S. (T). Dr Smart was highly respected and popular in the city of Liverpool and his death is a subject of general regret in the city and in the neighbourhood. The end was very sudden for he collapsed and died while conducting an examination of seamen at the Brocklebank dock.

NORMAN COLLUM PATRICK, M.R.C.S. Eng., D.P.H.

The death of Capt. Norman Collum Patrick, took place on March 24th in Belfast following a brief illness. As chief medical officer to the Ministry of Health Affairs of Northern Ireland, Capt. Patrick was an outstanding figure in the profession and was every

everywhere respected for the devotion with which he carried out his duties and for his kindly and sympathetic disposition. He was educated at Rossall and at Cambridge University and went for his medical training to St Bartholomew's Hospital. After his qualification he served as dispensary medical officer in the Glenties district of Co Antrim and subsequently was appointed tuberculosis officer for the county. At the outbreak of hostilities in 1914 he volunteered for active service and served through

out the greater part of the war as Captain R.A.M.C. attached to the 110th Field Ambulance 38th Ulster Division. After the war when the Northern Government was formed his professional ability was recognised by his appointment to the Ministry of Home Affairs and later in his rise to the rank of chief medical officer. His loss is deeply regretted by his associates at the Ministry and by many who found in him a loyal friend and a wise counsellor. He is survived by his wife and one daughter.

CORRESPONDENCE

POSTURAL DEFORMITIES OF THE ANTEROPosterIOR CURVES OF THE SPINE

To the Editor of THE LANCET

SIR.—The communication by Mr Philip Wiles published in your issue of April 17th comes at an opportune moment when a national policy to improve the physique of the people is being planned. Habitual use of the body with any real increase of the normal anteroposterior curves of the spine is undesirable. Mr Wiles states that voluntary control over the body movements that correct a postural deformity is easily taught when adequate mobility is present. In many cases however in view of the state of fatigue of the anti gravity muscles and the general lack of responsiveness it is not easy in my opinion to get these muscles to maintain an improved position. A period of reconstructive rest in bed for two or three weeks may be necessary as a preliminary to exercises. The mattress should be firm. The patient lies on his back with a low pillow beneath the head and knees at right angles and three times daily for half an hour after meals he lies on his thoracic spine is hyperextended by placing a firm pillow beneath it, the hands being clasped behind the head. This leaves the lumbar spine unsupported and exerts a slow corrective leverage upon the whole of the spine. It opens out the subcostal angle, and allows the patient to be instructed in correct breathing. The patient is then turned over to lie face downwards upon a pillow placed lengthwise beneath the trunk. Hot fomentations may be applied to the spine for 15 minutes, after which the patient resumes the first position described.

After ten days or so the improvement in the mobility of the spine and in the pliability of the muscles may be quite astonishing. Now is the time to begin spinal massage and instruction in a simple series of lying down postural remedial exercises designed chiefly to teach the patient how to flatten the lumbar spine and to contract the side abdominal muscles. Exercises in control are far easier to learn when lying down. It is now in order to allow the patient up for postural remedial training the object of which is to cause him to maintain an habitually improved attitude in standing sitting walking and breathing. As a useful temporary makeshift until the muscle sense of proper balance is restored, a slight spinal back brace to span the lumbar curve is often worn without it many quickly relapse into bad habits of poor posture and therefore no hesitation should be felt in prescribing its use.

The order of treatment then is reconstructive rest remedial training and support. The simplicity and lasting efficiency of these methods I have often proved in practice. They are not practised nearly enough. One hears a great deal about the active side of treatment such as massage exercises and so on and far too little in my view of the opposite or passive side which should precede and complete

the active side. Reconstructive, rehabilitating rest and support are just as important as exercises as a basis of restoration of correct use and function of the body. When the three weeks period of rest is over the patient should still for a considerable time have two half hour periods of hyperextension on the pillow daily. It is not a bad plan with slender physically delicate subjects to make a posterior moulded plaster of Paris shell in which the patient may lie at night or for part of the night. In aggravated cases it may be advisable to hyperextend the dorsal spine for a time upon an angled Bradford frame.

In the process of training it should constantly be remembered that in all body actions it is the head which leads in maintaining a proper static position. If the head is stretched up tall with the chin held in it causes the chest to be elevated and the diaphragm to work properly. It draws up the abdominal contents and gets the body forward on to the balls of the feet. The fixed elevated thorax thus assists in affording a strong basis of support for the action of the abdominal muscles. These muscles after all have to be allowed to assist the gluteal muscles in flattening the lumbar spine.—I am Sir yours faithfully

Edinburgh April 16th

W A COCHRANE

To the Editor of THE LANCET

SIR.—Your leading article last week on improvement of posture provided a valuable commentary on Mr Wiles' paper with an appreciation of the protagonist of correct posture—Goldthwait of Boston—not mentioned by Mr Wiles. The phrase "good body mechanics" first introduced by Goldthwait has helped me very much to crystallise the generally rather vague conceptions of what is to be gained by physical exercises. Since seeing the results of his theories applied in practice at the Robert Brigham Hospital in Boston I have taken the opportunity of studying and correcting the bad mechanics of incorrect posture at the Charterhouse Rheumatism Clinic. It is especially in rheumatoid arthritis and in spondylitis adolescents (Marie Strümpell syndrome) and even more so during the pre-spondylitic stage of bilateral sacro-iliitis, that the very simple postural exercises described by Goldthwait (1922-1934) have proved of immense benefit. I have adapted three for use all of which are performed lying on the back on the ground or other plane surface. As you yourself suggest this is the position which provides the necessary resistance to the flexors and support for the (weaker) extensors.

1 Hands behind head elbows pressed outward and down chest raised to the fullest extent. Breathe deeply 10-15 times without lowering the chest. According to Goldthwait and Loring Swaim this produces full diaphragmatic breathing empties the pleural cavity and enlarges the abdominal cavity by widening the subcostal angle.

2 When chest expansion is poor and the subcostal angle narrowed one hand is placed on top of the head

which is used as a fulcrum to pull on the ribs, first of one side, then of the other, as deep breaths are taken.

3 Hands to side, knees drawn up, the lumbar curve is straightened by using the glutei and "rolling up the pelvis" (as stressed by Mr Wiles). Maintaining this position, each leg in turn is straightened, lowered, and raised several times.

It is explained that these exercises are to encourage a correct posture to be maintained at all times. In Goldthwait's words "Stand tall, head up, chin in, chest high, abdomen flat, weight on balls of feet." These exercises take less than five minutes, and are far better than the usual "physical jerks" which occupy a long time, are extremely tedious, and are, I believe, of little value for the purpose of keeping fit.

I am, Sir, yours faithfully,

Harley street W., April 20th H WARREN CROWE

CYSTICERCOSIS AS A CAUSE OF EPILEPSY

To the Editor of THE LANCET

SIR,—In your issue of April 10th there is an account of an interesting and instructive case of cysticercosis (*T. solium*) which illustrates once more the importance of X ray examination of the limbs in the diagnosis of this condition, as calcification in cysticerci in the skull is not often seen. The statement, however, that "Morrison (1934) has described the only case where calcification of cysts in the brain associated with epileptic convulsions has been found" is incorrect. Dixon and Smithers (1934) collected all the cases of cysticercosis that they could trace as far back as 1892, and in 1935 published a fuller account of the condition in the *R.A.M.O. Journal*, in which they brought the total of cases up to 79 (46 of which had not previously been published). In this series of 79 cases 7 were found in which calcification in cysticerci could be demonstrated in skull radiographs. References to the original publication of these cases are given below.

Denny Brown's case was of particular interest in that it is, I believe, the only case on record in the English literature where calcified cysticerci were demonstrated in the radiographs of the skull but not elsewhere in the body.—I am, Sir, yours faithfully,

MEDICAL EDUCATION OF WOMEN

To the Editor of THE LANCET

SIR,—As long ago as 1934 THE LANCET mentioned that a proposal to establish a medical school for women at the West London Hospital was under consideration by the University of London. Dr Norah Schuster, in your issue dated April 17th, suggests that it might be of advantage to the West London Hospital to take women as students and she may be interested to know that the proposal is still having the careful consideration of the authorities both of the university and the hospital.

The creation of a new medical school is not an easy matter and it is no fault of either the university or the hospital that the women students of London, as also of Oxford and Cambridge, are still finding difficulties in getting vacancies in the London medical schools for the clinical period of training. This hospital can provide all the facilities necessary for clinical training and has been an active post graduate centre for over forty years. But we cannot accept

women students without the recognition of the universities for whose degrees they are studying. As far as the University of London is concerned I think I can say that this recognition is only being withheld until certain preliminary difficulties have been overcome. Every effort is being made to solve the numerous problems which are inherent in such a project, but the machinery of university government necessarily moves slowly and it is impossible as yet to give any indication as to the date upon which the change over from post graduate to undergraduate teaching will be made.

In the meantime this college continues to make its contribution to medical education as a post graduate school where increasing numbers of men and women from all parts of the Empire avail themselves of the excellent clinical material to be found in its wards and out patient clinics.

I am, Sir, yours faithfully,

MAURICE E SHAW,
 Dean, West London Post Graduate College,
 Hammersmith, London, W.

April 17th

OVER-TREATMENT OF GONORRHOEA

To the Editor of THE LANCET

SIR,—I should like to endorse the opinions expressed by Mr Nicholls in your issue of March 20th (p. 391) and by Dr Simpson (April 10th, p. 899) on the over-treatment of gonorrhoea.

A man of 26 who contracted gonorrhoea three years ago recently came under my care. He had been treated at a clinic for one year, by a doctor for another year, and by a second doctor for months. There was a little mucous discharge from gonococci but with many diphtheroids. The mucous surface of the anterior urethra was much scarred from treatment with Kollmann's dilator. He was suffering from a non gonorrhoeal urethritis due to prostatic calculi.

There is no more useful method of treatment than prostatic massage in the right cases and in the right amount, but much harm can be done both physically and psychologically if it is abused. If the patients are being overtreated the number of attendances at any one centre is unnecessarily increased. Should treatment be reduced to reasonable and proper proportions it might not be necessary to delegate massage of the prostate to the unskilled and sometimes rough hands of an orderly.

As regards women it is surely better for the woman with vaginal discharge to see a gynaecologist first than be sent by him to the V.D. department rather than as is customary at present, sent straight to the V.D. department to be sorted out. It is no doubt of great importance for the young gynaecologist to learn to operate skilfully but it is no less part of his vocation to diagnose and treat septic conditions of the cervix. The gratitude of many thousands of women is waiting to be earned by someone who can tackle this difficult subject.

I am, Sir, yours faithfully,

London W., April 15th

RICHARD ROPEL

LOCAL ANÆSTHETICS ON BLOOD-VESSELS

To the Editor of THE LANCET

SIR,—There is an inaccuracy which I would like to correct in your report (THE LANCET, March 24th, p. 756) of the discussion by the neurological section of the Royal Society of Medicine on the neuro sequelæ of spinal anaesthesia. Questions were asked by Dr Wilfred Harris and from the presidential chair about the vascular action of 5 per cent procaine solutions. Actually my reply was to the effect that while I used 10 per cent procaine

solutions intrathecally I had no experience of solutions stronger than 2 per cent in the skin and that such solutions in the absence of adrenaline coebefrin &c were vaso-dilator. The solutions used by my students in the practical classes are 0.1 per cent solutions of procaine and percaline with and without 0.001 per cent adrenaline.

As suggested by Dr Harris, I have since examined the effects of 5 per cent procaine (adrenaline free) both in and under my skin. Apart from the stretching of the epidermis by the solution no blanching is produced and considerable vaso dilatation follows. I have checked these observations on another subject and a dental friend assures me that similarly 5 per cent. procaine solution without adrenaline causes no vaso-contraction and only a brief anaesthesia when injected into the gum.

WHAT IS OSTEOPATHY?

To the Editor of THE LANCET

SIR.—Even the more vocal of the medical opponents of osteopathy are prepared to admit that certain conditions of strain or fixation which are often not demonstrable on X rays exist in the lumbar area. These joint conditions are sometimes accompanied by pain along the sciatic nerve or in the lumbar muscles. That a similar condition may exist in the cervical and upper thoracic areas and be accompanied by pain in the arm or shoulder has received attention in recent papers. It is equally an accepted fact that these conditions often yield to manipulation. Now the American trained osteopaths are exceedingly skilled in the quick specific movement of spinal joints, and because of constant practice and teaching their dexterity makes the efforts of the average orthopaedic surgeon look clumsy to a degree. Because of this dexterity the osteopath obtains much more satisfactory results in the long run with less discomfort to the patient and without having recourse to anaesthesia nearly so often.

It is accordingly submitted that even if all the other conditions which have benefited by osteopathic treatment are discounted the osteopaths have contributed something to the art of medicine and it behoves the medical profession to see that those among their members who set out to do manipulative work acquire a good pair of hands by practice and by taking every advantage of opportunities of seeing the work of experts at manipulation. It is just as foolhardy to entrust the manipulation of the cervical vertebrae to a general surgeon as it is to expect a radiologist to be able to perform a Wertheim hysterectomy.

AMBULANCES AND STRETCHERS

To the Editor of THE LANCET

SIR.—The question of standardising the size of British ambulances is one which I think deserves consideration. At present ambulances may be divided generally into short and long. The short type (most civil ambulances) is capable of carrying only short stretchers—i.e. those with folding handles—while the long type is capable of carrying stretchers with fixed handles such as the Army and St John Ambulance stretcher. In times of national emergency it would be most desirable that all ambulances should be capable of carrying any type of stretcher; otherwise

during an air raid for example St John Ambulance men having collected a casualty might find that they could not load him straight into the ambulance which had driven up. Delay is undesirable on such occasions and on all occasions the less a badly injured man is shifted about the better.

As the vast majority of British stretchers to day are of the long type—Army Air Force St John Ambulance and so forth—it appears desirable to encourage the production of long ambulances only, which could be relied upon for the rapid collection of all casualties at home or abroad. It is understood that the London County Council have already moved in this matter and our latest naval ambulances are long. I feel sure that if this aspect of the matter was brought to the notice of firms concerned they would advise their patrons accordingly when future orders were being considered. And as other countries suffer from the same difficulty this should become a matter for international consideration for there can be no question of international rivalry here.

TREND OF THE POPULATION

To the Editor of THE LANCET

SIR.—Please allow me to make the following comments on the valuable article by Mr C. A. Gould on p. 944 of your last issue. (1) The population of England and Wales has indeed been aging since 1870 but let no one overlook that this was due to reduction in the mortality of the young. (2) Mr Gould says that the population will attain a maximum of 40,800,000 about the year 1944 yet the Registrar General takes it to be more than that already. (3) It is not a serious matter that trade should decline if the amount of it per inhabitant increases. (4) The splendid diagram usefully shows that on the worst estimate the workers will outnumber the children and aged for a century so Great Britain should continue to have a high standard of living although it may cease to be a dominating power. I may add that if our farms become larger they will more easily compete with the food from the sparsely peopled countries and if wages rise there will be an increasing demand for home-grown produce. Mr Gould ignores the possible effects of migration but a relatively high standard of living would draw from the Continent as many young workers as we might choose to admit.

PAGE NUMBERS ON REPRINTS

To the Editor of THE LANCET

SIR.—From time to time I am the fortunate recipient of reprints of papers which have appeared in various periodicals. May I call attention to a not uncommon fault in these reprints? It is the omission of the number of the first page of the article. I have before me a reprint from a well-known scientific publication. It gives the name of the journal, the number of the volume, the number of the issue and the date of publication but no page. In a country like this it is impossible always to get into touch with a library to supply the omission and in my editorial work I find the impossibility of inserting the page number a difficulty in carrying out properly the Harvard system of references.

I am Sir yours faithfully

JAMES H. SQUYER

Nairobi, Kenya March 27th

PARLIAMENTARY INTELLIGENCE

CORONERS AND THEIR DUTIES

In the House of Lords on April 15th Lord MORRIS said there was an increasing tendency among coroners to moralise and lecture at inquests over which they presided and he inquired whether steps could be taken to curb this undesirable disposition by legislation. Alternatively, he asked the Government if they would consider the abolition of the ancient office of coroner. In February, 1935, the then Home Secretary, in response to popular clamour, had appointed a Departmental Committee to inquire into the law and practice relating to coroners. In the course of its report it was stated —

The tendency of some coroners to animadvert upon the conduct of persons who have, perhaps quite incidentally, come under their notice has frequently been the subject of public comment. We consider that the practice should be brought to an end. We do not, however, propose any amendment of the law at present on this point. We believe that the body of our recommendations, taken as a whole, will tend to put a stop to this practice.

That pious hope unfortunately had never been fulfilled. The present Home Secretary had also quite recently expressed a similar hope that coroners would have some regard to the recommendations of that Committee. On the contrary, coroners had paid no attention whatever to those recommendations, but were getting worse. For example, a month or two ago the coroner at Greenwich had publicly rebuked a minister of religion and lectured him on his supposed duty. On March 23rd the coroner for Tunbridge Wells, inquiring into the death of a six-weeks' old child, told the mother *coram populo* this —

This child was starved to death, but I am prepared to believe that you thought you were doing the right thing. I am prepared to put your complete failure down to ignorance. You and your husband are both young, and I hope you make a better job of it next time.

Lord MORRIS suggested that that was a piece of intolerable impertinence. It was time that a stop was put to this kind of thing and that steps were taken, if necessary by legislation, to check this desire on the part of coroners to apportion moral responsibility, an act that had nothing to do with their proper function, which was solely to inquire into the cause of death. At Harrogate a short time ago the local coroner was inquiring into the death of a man. According to the *Yorkshire Post* the son of the dead man said "I would like to make it perfectly clear that my father was living a mode of life which he was not accustomed to." The coroner remarked to the son of the dead man "I know all about that. You have the gentlemen of the press here, and certain papers will thoroughly enjoy spreading your family troubles all over the country. If you will take my advice you will say nothing more." Lord MORRIS said he thought that a man who could so abuse his position as to make remarks of that kind was quite unfit to occupy the post of coroner and the sooner he was removed the better.

The coroner's court was admittedly very old in origin, it went back, he believed, to the thirteenth century, but that hardly seemed a reason why it should survive to day. There was now an efficient police force and the coroner served no useful purpose whatever. He was merely a nuisance and an expense, he cost the country, on an average, not less than £220,000 per annum which might be put to a better use. The only possible case where inquiry of this kind was called for was in suspected foul play, and these could well be left in the hands of the police. There was objection to that in some quarters on the ground that the police might be corrupt or negligent. He did not think that fear was well founded, but a coroner's inquest was certainly a very indifferent safeguard against that danger,

if it be a real one. Leaving out these cases they remained those of obvious suicide, motor accidents, and so forth. Deaths due to road accidents could very easily be investigated by the Ministry of Transport, and railway accidents could be inquired into—as indeed they were at present—by the coroners in question. In almost all cases of fatal accident to employed persons—taking the mining industry for an example—these inquiries were now carried out by experts, and the coroner's inquests did not throw any light on the matter at all. The coroner was nothing but a paid public Paul Pry and the whole thing was extremely un-English. The very expensive but undoubtedly interesting travesty last year when one of their Lordships was tried on a charge of manslaughter was due entirely to the fact that the noble Lord in question was committed for trial there on a coroner's warrant, and no magistrate would have committed the noble Lord at all, since there was not a tittle of real evidence against him. He was convinced that there was a growing and considerable volume of opinion in this country which favoured the complete abolition of the coroner and his inquest.

Lord SNELL said that the issue which Lord MORRIS had raised was not an unimportant one. They expected public officials in this country to do their duty according to their obligations to the State. It was true that very few of them could resist the temptation to advise another person when he was in trouble, but they did not appoint public coroners for that purpose. They had certain specific legal duties to perform and when those duties had been performed the coroners had done all that the nation expected of them. The very worst moralist in the world was the amateur moralist who knew practically nothing about it and he thought that Lord MORRIS had made the point that coroners should stick to the job for which they were appointed and leave the matters to the discretion of people whose knowledge upon them was superior to their own.

The MARQUESS OF DUFFERIN AND AVA, Lord-Waiting, said that Lord MORRIS had made so many accusations that it was difficult to keep track of them. For instance, he had said that the coroner's court was un-English. No habit or practice of this kind was called English until it had been sanctified by custom for many years, but the coroner's court went back to 1276, and he thought that the noble Lord would agree that this un-English custom had very small roots in our land. He did not want to quibble, but he must say on behalf of the Home Office that the words of Lord MORRIS's question were extremely misleading. So far as the Home Office were aware there was no increasing tendency on the part of coroners to moralise and lecture at the inquests on which they presided. The press and the public were very vigilant at the moment with regard to the way in which coroners exercised their responsibilities, and the Home Office would certainly have been aware if coroners had in fact tended to spread themselves more in the last few months than they had done in the past. Lord MORRIS had really only argued from the cases which had come to his notice in the public press and, of course, the only cases which had come to his notice were cases where coroners had exceeded their responsibilities. He had given credit at all for the number of inquests, tens of thousands of them, that were held in this country in which the coroner had acted properly and rightly. There were 3500 inquests held in London alone every year. Lord MORRIS. What a waste of time. The MARQUESS OF DUFFERIN and AVA said it might be a waste of time, but so far as he knew during the last year no complaint of any coroner's conduct at any of these inquests had been made. At the same time it was not for him to deny that on occasions the privilege of the Coroner's Court of Record might be abused. There was, of course, a grave danger, and

it was all the graver because sometimes these lectures and moralisations were directed at people or at institutions who were not able to answer back and might not even be present in the court or not represented by people qualified to deal with the intricacies of the law. He need hardly say that the Home Office took the very gravest view of that sort of attack. The Home Secretary recently in the House of Commons had used what seemed to him rather hard words. They made it quite clear that in the view of the Government spitting on the grave of the departed did very little good. The grave could take care of its own, but the living must be considered. In the view of the Government and of course, of Lord Wright's Committee a living man had just as much right to have his reputation protected as his liberty and it was just as wrong to take away a man's reputation without due process of law as it was to take away his liberty. That point was the occasion of a circular issued by the Home Office in 1927 to all coroners in which the Home Secretary made it clear that as he had been pressed to make a rule on the subject

He may say that where it is possible to secure the attendance of a person whose conduct appears to be in question it is desirable that his presence should be secured before censure is passed and that he should be afforded a reasonable opportunity of making any relevant explanation. It need hardly be added that there is special need for care before publicly making adverse comments if the person concerned is likely to suffer thereby in his profession or calling.

That circular was followed by the recommendations of Lord Wright's Committee which were naturally brought to the notice of coroners and he firmly believed that the mere publication of the Committee's report had done much to curb the habit to which Lord Morris objected. The Committee expressly added that on this particular point no legislation was required. They expected that the legislation that might follow from their report in regard to the Disciplinary Committee and the Rules Committee would be sufficient to attain their object. Lord Dufferin assured Lord Morris that although the programme of legislation was very full and he could not possibly offer any concrete promise at the same time when opportunity offered the suggestions of that Committee would probably be the subject of future legislation. When that happened he was perfectly certain that all the evils of which the noble Lord had complained would be done away with. The Government agreed with his noble friend in this so far as they deprecated coroners going outside their proper function. At the same time with the Wright Committee which was very definite on this point, they could not possibly contemplate the abolition of this ancient office.

DEFECTIVES AND VOLUNTARY STERILISATION

On April 18th on the motion that the Speaker do leave the chair on the House of Commons going into Committee of Supply on the Civil Estimates (Wing-Commander JAMES moved the following amendment—

In the opinion of this House the Government should give further consideration to the potentialities of voluntary sterilisation for hereditary defectives in accordance with the unanimous recommendations of the Departmental Committee that reported to the Ministry of Health on Jan 8th 1934.

He quoted a paragraph from the report of the Committee on Scottish Health Services which he said was a very strong body and the most recent health committee to report. It said: "In considering what measures should be taken to improve the health of the people we have to take into account at the outset the question of heredity. Physical and mental capacity has a basis in inheritance and some people therefore because of their hereditary constitu-

tion will be less fit, physically and mentally than others no matter what is done by way of medical care and improvement of environmental and other conditions. He (Wing-Commander James) invited the Minister of Health to give his attention to the need for further research into the problem of genetics. The fact that the amendment was not completely in agreement with the recommendations of the Brock Report was not because he disagreed with any of them, or would depart in any respect from them, but was merely a matter of technical form. Mental deficiency which covered the largest number of people concerned had generally in varying degrees a basis in heredity. In the Colchester inquiry it was shown that heredity played the greater part or the lesser part in the predisposition to mental deficiency in approximately 91 per cent of the cases examined. In addition to mental deficiency there were other forms of hereditary disability notably some forms of blindness which was much more directly hereditary even than the average form of mental deficiency. Most of the opposition to the idea of sterilisation came from people who had not read the report of the Brock Committee. That committee agreed with the Wood Committee, which published a report in 1920 that there were in England and Wales about 300,000 defectives and they gave it as their opinion that of that number approximately 200,000 were fit for community life, their degree of deficiency or defect not being high enough to justify their being retained in any form of institution. At present a very much smaller proportion than one-third was in fact in institutions or under care.

On Jan 1st 1936 the London County Council published a report containing the statement that the London County Council Hospitals Committee was responsible for the care of 27,730 persons of both sexes. In an earlier report they stated that 30,000 beds were occupied by deficiency cases. They stated further in the 1930 report, that since 1920 there had been an average annual increase of 803 and that during the next few years they anticipated a net annual average increase of 560 in the number of persons for whom accommodation would have to be provided. The increase recently was partly due to the growth of population of the London County Council area. The expenditure on such cases by the London County Council during the last financial year was £1,808,933. There was an enormous total expenditure in connexion with this problem. He did not suggest that if sterilisation were legalised it would be an economy. In the long run that might be achieved; but it was not from the point of view of economy that the Brock Committee recommended sterilisation or that anyone else should consider the problem. If sterilisation were legalised the immediate effect would be small. But if any part of the present enormous expenditure could be diverted to other channels and social services the community as a whole would benefit. The Central Association for Mental Welfare actively supported the suggestion that sterilisation should be legalised. A point in opposition to this proposal was that the existence in the community of persons who had been sterilised would lead to a lowering of the standard of morality. That point was examined and answered by the Brock Committee. There was still a great deal of misunderstanding about the nature of the sterilising operation. Any doctors who might be present that day would confirm the statement that the operation was very simple. In males it was trivial and wholly unattended by risk and in females it was virtually unattended by risk. It had no effect whatever on the normal ordinary life and health and capacity of the individual. It had nothing in common with any of the operations used for the removal of any gland. It in no way affected sex life or sexual secretions. The only effect was that the sexual act when performed did not result in fertilisation. Another argument frequently used against the recommendation of the committee that sterilisation should be legalised was that a mentally defective

person cannot have full volition. That argument, again, was dealt with extensively in the report. Sexual sterilisation to-day for health reasons as opposed to eugenic sterilisation was perfectly legal. Every year hundreds of people in this country had such operations performed either by private practitioners or in general hospitals for reasons of their own health. Most frequently this occurred with women likely to be endangered by child-bearing. But it was illegal for a person to be sterilised in the interests of posterity—or it was probably illegal, because it was not settled as a matter of case law or statute law.

Of the 300,000 defectives estimated to be in England and Wales, 200,000 at least conducted their lives in the ordinary way as members of the community and for all other purposes save this were held to have volition. Then there were people who had hereditary disabilities. Was it to be said that they had not complete volition? There were also carriers, themselves sound, whose progeny might well suffer from some congenital trouble. There was one point by which the Brock Committee was very much impressed—the position of the unfortunate normal child of a defective parent. It was perhaps one of the most telling arguments in favour of sterilisation.

One of the obstacles to this desirable reform arose from the opposition of the Roman Catholic Church. Fifteen years ago the whole question of sterilisation was brushed aside as so improper, so unthinkable, and so impracticable as to be unworthy of argument. Public opinion had moved a long way since then, and with it that great Church, which for generations had moulded and directed so much of human thought but which, he believed, had never in the long run stood across the path of progress, had modified its position. There was no reason why, if the Papal authorities decided to do so, they should not with perfect consistency change their attitude on the subject. It was a matter of discipline only and not of dogma. Since no responsible authority in this country had ever advocated sterilisation being anything but voluntary, and since, therefore, there was no possible suggestion that it could be inflicted on anyone, why should the Roman Catholic Church deny to those who were not Roman Catholics a form of relief which they desired? There had been much less opposition to the idea in the country than was supposed, and particularly among the poorer classes, who were the people who suffered most from the proximity of defectives and comprised the class which could not afford the use of nursing homes, there was a fervent demand for the legislation of sterilisation. The present position was class legislation. Those who were well off could get themselves sterilised if they wanted to, and those who are not well off cannot do so.

Some of the more important bodies which had recently signified their support of the principle of voluntary sterilisation included the Royal College of Physicians, the Royal College of Surgeons, the Society of Medical Officers of Health, the Mental Hospitals Association, the Women's Public Health Officers' Association, the County Councils Association, the Association of Municipal Corporations, and many others. He hoped that the Minister of Health would be able to give some statement on what was being done about the research recommended by the Brock Committee and incidentally by other bodies, such as the Departmental Committee on Scottish Health Services of 1930. There were now many countries abroad which had on their statute books and in practice sterilisation laws. Those countries included Germany, the Scandinavian countries and some British Dominions. Those who advocated voluntary sterilisation did not for a moment suggest that it was going to be a universal panacea or a substitute for other efforts. All they said was that for those who wanted it administered under adequate safeguards such as were recommended by the Brock Committee it would be a most important and very necessary weapon in the armoury of preventive medicine.

SIR FRANCIS ACLAND, in seconding the amendment, said that the more he had studied the question the more convinced he had become that something ought to be done without too long a delay. He emphasised a point implicit in the whole campaign for voluntary sterilisation on the lines of the Brock Report, namely, that this campaign was not, as it had been represented to be, the thin end of the wedge towards compulsory sterilisation. It was the very reverse and antithesis of the whole idea of anything compulsory. The proposal was not that anyone should go and get himself or herself sterilised, but that there must be very careful inquiry and certification by two doctors, who were both specially approved for the purpose, with an expert Ministry of Health committee in the background in case the Ministry's advisers were not satisfied with the medical report and certificates. That had this importance that three out of four classes who would be entitled to apply for voluntary sterilisation under the Brock Report, the certificates could only be given if the practitioner were satisfied that the person applying was suffering or had suffered, from disability or disorder deemed to be inheritable, or was a person deemed to be likely to transmit defectiveness or disorder of great disability to a subsequent generation. It was a really honest opinion with regard to that could be formed unless the practitioners concerned had access to the family histories of both of the generations and of the collaterals of the person concerned. No one would give information if it was any possibility that a person might be sent out and compulsorily sterilised. Therefore the whole machinery on which voluntary sterilisation rested which depended on the care and conscientiousness and thoroughness of these reports, would be brought to naught immediately any system of compulsory sterilisation was introduced.

Mr LOGAN said that the teaching of the Church was that man was made to multiply, and there was no getting away from that special ordinance. If a measure could not be applied unless it was compulsory. It was a very bad thing for medical men to advocate sterilisation in view of the advances in science, and he suggested that they would be doing better to give attention to raising the standard of life for the worker.

Captain GUNSTON said that the Brock Committee reported that "The children of parents one or both of whom are mentally defective are, on the average, below the normal, and our inquiry shows that more than one third of such children as survive are likely to be defective, and more than two fifths must be expected to exhibit some degree of abnormality." In the face of evidence like that, it could not be said that they ought not to take measure to reduce the number of mental defectives born into the world.

Mr PRITT said that this was a very fundamental step to propose and further research was really a proper course. He understood that on the whole the results so far in the United States where voluntary sterilisation had been seriously applied had been little disappointing from a statistical point of view. The results in Germany really ought to be ruled out entirely, because they had not been going very well, and were obviously administered with such motives and such reckless disregard of decency that it would not be fair even to use them as an illustration of the abuses that might result in a civilised country.

SIR KINGSLEY WOOD, Minister of Health, said that an allegation had been made that there had been an increase in the number of defectives in this country. Of course it should be borne in mind that the number of defectives under care increased as the general population increased, and as the local authorities became more efficient in ascertaining the existence of defectives, but it could be said with authority that there was no proof that the incidence of mental deficiency in this country was rising. Reference had also been made to what had been done by other countries and he assured the House that, of course,

his Department and the Board of Control kept them selves fully informed of the progress made under foreign statutes. But it could be said with accuracy and truth that at any rate up to the present time no results of significance could yet be assessed. For instance a system of voluntary sterilisation was approved in Norway and also in Sweden in 1935. Germany brought in a compulsory system of sterilisation in 1933. Although Denmark began a system, as regards a limited class in 1929 again no useful lessons could be learned from it. Members would appreciate the importance apart from the merits of the case of taking public opinion wholly with them. Sterilisation laws were in operation in several of the United States but in some little use had been made of them. In certain cases the law appeared to have been enacted without any money being provided to work them but the real explanation of failure in other cases was probably that the enthusiasm of small groups secured the passage of legislation for which there was no general demand and no sufficient backing of public opinion.

Observations had been made in the debate which would lead one to think that perhaps in certain cases the treatment of people who unhappily suffered from this terrible disease was, to quote one expression used, very horrible. He would like anyone who came across a case of that kind to give information at once. He shared the view of a good many people of what a terrible tragedy it was and what it must mean to people concerned. But he must testify to the increasing provision care, forethought and kindness displayed in these institutions. He would not like it to go out that there was anything else but the utmost consideration shown and large sums of money spent to see that reasonable care and treatment were given. Undoubtedly a great deal had been done. For instance only in 1934 in consultation with the Board of Control the Medical Research Council appointed a new committee to advise and assist them in promoting research into mental disorders. Another committee of equal importance had also been appointed by the Medical Research Council a committee on human genetics because in spite of the advances made in the biological study of heredity and the application of the results it was felt that the study of human genetics had been relatively neglected. Under theegis of this latter committee some very interesting researches were now taking place at the Royal Eastern Counties Institution at Colchester by Dr Penrose and his colleagues and an important examination of the hereditary characteristics in the blood of mental defectives and their families was now being made by Prof Fisher and Dr Taylor of the Galton Laboratory University College London. This work was being assisted by grants from the Rockefeller Foundation. Dr Slater at the Maudsley Hospital London was also working on a large-scale field of inquiry into certain different types of mental disorder. Other work was also being carried on so that it would be seen that this aspect of the question was not being neglected by the Government.

Wing-Commander JAMES asked if the Minister could give an assurance that any funds needed for research would also be forthcoming from the Government?

Sir KINGSLEY WOOD said that would be a very bold undertaking to give without consultation with the Chancellor of the Exchequer but if a question of money arose which he (Sir K. Wood) thought was important he would not hesitate to take it to the Chancellor of the Exchequer. He could say from his knowledge of many years now in connexion with health work that there was no doubt that opinion was growing in favour of sterilisation. When he came back to the Ministry after an absence of some time he saw the record of a deputation from the County Councils Association and the Association of Municipal Corporations in 1935. They represented a large body of people discharging responsible duties in a wide field of public and social work. It would have astonished a great many people if such a deputation had taken place

only two or three years before. But he could not disguise the fact that opposition still remained and there was much conflict of opinion particularly on religious grounds. The medical profession were by no means unanimous on the matter. If one asked even the medical men that one knew in one's private circle there was not a great deal of unanimity of opinion. Resolutions of certain learned colleges had been quoted but he very much questioned whether one would get anything like unanimity from the British Medical Association.

Mr THURTELL asked if it was not a fact that on most matters one could not get unanimity in the medical profession.

Sir KINGSLEY WOOD said there were always small minorities and one dealt with them as best one could but there would be found, he thought in the British Medical Association, a pretty steady and strong view on most medical matters of the day. He was endeavouring to put fairly the other side of the matter and he doubted very much whether they would get such a strong vote as would justify a Bill being promoted at this moment. It was desirable that ample time should be given for consideration and to get public opinion developed as he believed it was developing.

Wing-Commander JAMES withdrew his amendment.

NUTRITION: NEW GOVERNMENT SURVEYS

On April 13th in the House of Commons Mr ROWSON said that there could be no doubt that there were many people in this country suffering from a shortage of essential foodstuffs. The case was proved and accepted that large numbers of people were suffering from malnutrition. The Ministry of Health was certainly the best department through which they could act if they desired to improve conditions among the people. They should extend as far as possible the drinking of milk and also give advice on the right kinds of foodstuffs. He would like to see through the health committees of the local authorities a more widespread use of the valuable food that was produced and if necessary free distribution among the child population. The Minister of Health should do something with a view to organising the better feeding of children in the schools. He hoped the Minister and all Members of the House would recognise that this was a problem which must be faced. There was intense suffering all over the country and they ought to do their best to remedy this terrible evil among the people.

Sir KINGSLEY WOOD said he welcomed this discussion because it came at an opportune moment and he seized the opportunity to call the attention of Members to the publication of the first report of the Advisory Committee on Nutrition of the Ministry of Health. That was the most valuable document on nutrition that they had had up to the present time, and there could be no question as to the authority of the committee and its report was unanimous. It served a very useful purpose at present in that during the last year or two the question of nutrition had not only been a subject of much discussion but one on which all sorts of confusing statements had been made about the condition of the nation. The committee said that a great deal of further information on the facts must be obtained before they could reach a final national policy on nutrition. The report was particularly valuable in that it pointed out a number of ways along which they could make many advances. But while nutrition was an important side it was only one side of our national health problem. A man did not live by calories alone; the national health did not depend only on vitamins, but on a steady pursuit of many objectives such as better housing, the clearance of slums, maternity and child welfare, the provision of more open spaces and physical recreation. To-day no word was more often used and abused than malnutrition. Members should read Dr McGonigle's book in which he gave a very fair description of what malnutrition really meant.

On their broad survey, the Advisory Committee had come to the conclusion that the consumption per head of most foodstuffs had increased since the war, and the weakest thing to which they could point in connexion with the national dietary was the consumption of milk which is on a very low level in this country. The consumption per head had slightly declined since before the late war. Milk was the most complete food known and that there was no single step which would do more to improve the health and the resistance to disease of the rising generation than a largely increased consumption of safe milk by mothers, children, and adolescents. They found that, on the average of the years 1934 and 1935 all except a relatively small part of the population were obtaining the full amount of calories which they required. The national diet also contained enough protein, provided the consumption of animal protein increased, while that of vegetable protein remained nearly constant, as the standard of living rose with income. Sir Kingsley had asked each local authority to review at an early date its arrangements under the Maternity and Child Welfare Acts for the supply of milk and other foods, in view of the importance of securing that the diet of expectant and nursing mothers should contain the proper constituents and that the consumption of milk, especially by young people, should be increased. Practically all local authorities had already made some arrangements for the supply of milk, and many also for the supply of other foods, but it was essential that this important matter should be adequately dealt with throughout the country.

He had also drawn the attention of the authorities to the fact that there was to be no question of the limitations. He had told the authorities that he did not think it desirable to adopt any such restriction, for instance, as limiting the supply of milk to the last two or three months of pregnancy only, or only to children up to the age of 18 months or 2 years, or in every case to a pint per day. It was also very important that the scales of income should not be framed so as to render it difficult for any mother to take advantage of the authority's arrangements. Wherever possible efficiently pasteurised milk should be provided, and that where this was not practicable the medical officer of health should approve of the source and quality of the supply. He had also asked the authorities to consider afresh the question of a properly organised system of meals.

In some areas local authorities had hesitated on grounds of financial stringency to develop these services as fully as they desired to do, but the additional financial assistance afforded by the recently passed Local Government (Financial Provisions) Act provided a further reason for an early review by the authority of existing arrangements. The block grants to local authorities had just been raised by £5,000,000 to nearly £50,000,000 a year and at any rate the rearranged distribution gave a larger share to the authorities whose need was greatest. Therefore, he considered that many of them would be able to continue and extend the work which they were doing in the direction indicated by the Advisory Committee.

The Advisory Committee had asked for certain further information before they issue their next report. The Minister of Labour was shortly to undertake a family budget inquiry to provide the material required for a revision of the basis of the cost of living index. This was going to be incorporated in the Ministry of Labour cost-of-living inquiry which would involve the collection of budgets from 10,000 families for one week, and from the large proportion of those families for three other weeks, and also supplementary budgets of personal expenditure from wage-earning members of the families. They thus hoped to be able to obtain the further information asked for by the Advisory Committee. They also proposed to make certain dietary studies which were

recommended by the Advisory Committee, some of which would naturally take a considerable time.

Mr E J WILLIAMS said that Dr Somers Hastings, speaking recently of the inspection of children under the school medical service, had said that six minutes was taken to examine a school child, and he had complained that it was quite impossible to find out the flaws in a child's health in six minutes. Mr Williams asked the Minister whether something could not be done to give more accurate information as to school-children's state of health than we had at present. He hoped what Dr Hastings had said would be examined by the Department, to see whether it was possible to find out the actual physical state of a child in six minutes, including the time in which a report had to be written on the child's condition. Yet the figures presented in reports on the condition of school-children in this country were dependent on such scanty examination as that. They did not really know the physical state of school-children, and with such inadequate medical examinations they could not hope to know it. The Minister should insist that the school medical service was treated in a more scientific way than existed to-day.

Mr A. V. ALEXANDER said that the policy which the Government had adopted was not touching the problem. The Minister seemed to take pride in the fact that there was to be a further inquiry into family budgets. In the inquiries at Sheffield, Liverpool, Manchester, Salford, and that of the British Medical Association, they had an abundance of material available about what dietaries cost the householder for the Government to take any necessary action if they liked. It was simply a long-drawn-out process of appointing inquiry after inquiry instead of doing what was essential, enabling the people concerned in one form or another, either by improved wages, or by increased assistance or by adequate scales for those who had recourse to public assistance to be able at least to purchase the minimum standard of food required to set up a proper basis of nutrition. There was sufficient evidence already to show that the increased cost of basic dietaries to-day was so great as to justify the special attention of the Government to the income of the families which had to obtain their food.

Mr R. S. HUDSON, Parliamentary Secretary to the Ministry of Health, replying to the statement that the results of an examination of school children could not be of very great value because the time taken for the examination was only six minutes, said obviously it was impossible to have a proper examination in that time, said he was told that in fact the time taken for the examination was not six minutes and that the examination of some of the children took a longer time and that of others less time, the average being six minutes, which was adequate for the purpose. It was absurd for Mr Alexander to say that as a result of something the Government had done the people in this country were seriously prejudiced in obtaining adequate food. In some of the reports of Lancashire medical officers of health dealing with the health of school-children in Lancashire, one of the most reassuring things which emerged was that even in the boroughs in Lancashire where in view of the long-continued distress which many of these boroughs had suffered one would have expected to find high rates of malnutrition and starvation among school-children, actually one did not find that. Anyone who knew Lancashire would know of the great amount of unemployment and suffering which St Helens had gone through recent years. The medical officer of health for St Helens reported last year—and there was a question here of averages—that out of a total school population of 5797 who were examined he only found eight individual school-children suffering from malnutrition.

The motion that the Speaker do leave the chair was carried by 161 votes to 120.

FACTORIES BILL IN COMMITTEE

THE Factories Bill was further considered by a Standing Committee of the House of Commons on April 18th. Major LLOYD GEORGE was in the chair.

On Clause 85 which deals with the procedure at inquests in the case of death by accident or industrial disease in a factory.

Mr MANDER urged that where a coroner directed a post-mortem examination of the body of any person whose death might have been caused by accident or disease the various interested parties should be entitled to be represented by a medical practitioner. He said that there was considerable anxiety on this point and it was the subject of a recommendation in the report on the question of coroners. Mr SILVERMAN said he had had professional experience very recently of a case which threw a great deal of light on the point raised by Mr Mander. A man who had contracted silicosis was granted a workman's compensation award on the basis of total incapacity under the silicosis scheme. After a considerable time the man died and prior to the inquest there was a post-mortem examination conducted by the surgeon who had been requested to act by the coroner. The surgeon's evidence was that the man had died from silicosis and a verdict was returned to that effect. He (Mr Silverman) understood that at the post-mortem portions of the lung were detached and sent as was the custom to the Silicosis Board and some little time afterwards there was a decision by the Board that the man had not died from silicosis but from tuberculosis accompanied by silicosis. Therefore no compensation to the widow was payable. From the decisions of the Board there was no appeal. If Mr Mander's suggestion was agreed to in such cases the widow would be represented at the post-mortem and the inquest Mr LLOYD Under Secretary Home Office said that it seemed undesirable to deal with the post-mortem procedure in this Bill. The Coroners Committee made various recommendations on the subject which ought to be considered as a whole. It was suggested therefore that this matter should be left to be dealt with by further legislation when it could be looked at as a whole and in perspective.

The clause was ordered to stand part of the Bill. On Clause 87 (Duty of examining surgeon to investigate and report in certain cases).

Mr LLOYD, replying to questions in regard to this clause, said the surgeons were designated examining surgeons instead of certifying surgeons. He would look into examining surgeons. He would look into the matter in consultation with his advisers at the Home Office before the report stage.

The clause was ordered to stand part of the Bill. On Clause 88 which provides among other things that subject to certain exceptions the total hours worked by women and young persons in factories, exclusive of intervals for meals and rest shall not exceed nine in any day or 48 in any week; that the period of employment shall not exceed 11 hours in any day and shall not begin earlier than six o'clock in the morning or end later than eight o'clock in the evening or on Saturday one o'clock in the afternoon; and that where women and young persons are not employed on more than five days in the week the total hours worked may extend to ten and the period of employment may extend to twelve hours in any day.

Mr RIDLEY moved an amendment providing that it should not be lawful to employ a young person under the age of 15 in a factory. He said that doctors objected to the Clause as it stood because by it sleep was denied and educationists did not want it because it education was denied. No one wanted the Clause except the bad employer.

Mr DIXON said that to the general proposition that a young person below the age of 15 still growing and developing should not become part of a machine

and work long hours still required under this Bill he thought the whole Committee could almost unanimously agree. But there was a real difficulty here. The new Education Act did not come into force until 1939 and therefore there would be a years gap. While there was nothing to prevent the children staying at school during that interval they had to face the fact that they would leave school in large numbers and if this amendment were passed they would be prevented from getting into the best available occupations at that age. He agreed that they should strive for the time when children would be kept at school and not be allowed to go out into the labour market so early but while they were on the labour market it would be a mistake to decline to let them enter what were frequently some of the best occupations.

After further debate

Sir JOHN SIMON Home Secretary said that the Committee had now reached one of the really important parts of the Bill. He had taken the view from the beginning that in some respects the measure called for a change of drafting. Clause 145 (which deals with general interpretation) as the Bill stood stated: "Young person" means "a person who has attained the age of fourteen but has not attained the age of eighteen." They had to remember that Parliament had passed a new Education Act and the Factories Bill must be drafted in a form which fitted the Education Act. Therefore the Government had put down an amendment to add to Clause 145 the following:—

"But does not include any person whose parent is required under or by virtue of the Education Acts 1921 to 1936 to cause him (unless there is some reasonable excuse) to attend school or to attend an alternative course within the meaning of the Education Act 1936."

That he thought was the proper way in which to ensure that the provisions of the Education Act should be consistent with the factory law. Since the Factories Bill was introduced the Committee on Unregulated Occupations had reported and it dealt with various classes of young persons including van boys and others employed in connexion with factories. The Committee recommended that there should be regulation of the hours of work for young persons employed in connexion with factories, docks and warehouses. It further suggested that it might be possible to introduce that into the present Factories Bill. As far as he (Sir J. Simon) could see it ought to be possible to do that and if so it would stop an important gap. He was sorry that in the circumstances he could not offer to do more in this matter than he had said.

Sir ERNEST GRAHAM LITTLE said that there was one very important argument that had not been used and that was in connexion with the diminution in the number of children in the country. The capital which the child population represented was the most important capital that a nation could possess. Let them make sure that they did the very best for that capital which was possible. If they were going to deprive children of adding to their education it would be uneconomical and foolish.

The amendment was still under discussion when the Committee adjourned.

Debate on the amendment was resumed when the Committee met on April 15th.

Replying to a number of speeches

Mr LLOYD said that there was no justification for saying that in no circumstances could it be regarded as beneficial for juveniles between 14 and 15 to go into factory employment. The Board of Education had undertaken that in a circular which they were issuing to local authorities they would draw special attention to the importance of the permanence of employment being regarded as one of the considerations to be borne in mind in determining whether the employment was beneficial or not. The proposal in the amendment would completely hamstring the arrangements made under the new

Education Act. It was not a practical proposal in the interests of the juveniles and it cast an unjustifiable slur on factory employment as such.

After further discussion the amendment was negatived by 32 votes to 22.

Mr RIDLEY moved an amendment to the same clause to make its provisions apply to all workers in factories.

Sir J SIMON, in opposing the amendment, said it was a novel proposal. It was a suggestion to establish by law, for the first time in this country, the maximum number of hours to be worked by a grown man in a factory. In the past there had been collective bargaining between the trade unions and the employers and the law had only limited the hours of work in relation to certain classes of people because it was thought that they were in special need of protection.

After a long debate the amendment was negatived by 29 votes to 16.

The Committee adjourned.

HOURS OF EMPLOYMENT IN HOSPITALS

ON April 14th in the House of Commons Mr KIRBY asked leave to bring in a Bill to provide for the limitation of hours of work for persons employed in or in connexion with hospitals and institutions under the control of local authorities. He pointed out that the measure did not apply in any way to voluntary hospitals or institutions of that character. He and his friends would desire that it should cover those voluntary institutions as well but they realised the difficulties that a Bill of this sort might bring to them and therefore they were deliberately excluded. The Bill provided for a working week of 48 hours for the outdoor staffs and in the event of urgency or emergency those hours might be exceeded, providing that overtime was paid at the usual scales as provided for in agreements between employers and workpeople. So far as the indoor staffs were concerned the Bill provided for 96 hours' work in each fortnight with the same provisions for overtime as applied to the ordinary outdoor staffs. He thought it would be generally agreed that so far as the nursing and other indoor staffs were concerned it was desirable that not too strict a line should be laid down in order that the emergencies of the nursing services should be provided for if necessary. With a 96 hours' fortnight instead of a 48-hours' week there would be a much wider scope for the indoor staff in their various duties and shifts than if it was confined to a 48 hours' week. He believed that provision would be a special boon to the smaller institutions and hospitals where they had a very small number of personnel to deal with. The other provision of the Bill was that every worker whether employed on the indoor or outdoor staff should have a rest day in every week—a full 24 hours off duty for every calendar week worked.

The conditions in hospitals and institutions of a similar character had been widely investigated during the past two years and those investigations showed that there was chaos generally in the management, which required rationalising and regularising in a great number of ways and particularly in regard to hours. At the present moment those people who worked outside these institutions—motormen and ambulance attendants—by reason of the fact that they were in a trade union enjoyed better hours and conditions of labour than many of the nursing staff employed inside and he was particularly anxious that so far as the inside staffs were concerned this Bill should become law very soon. He would give the House two quotations from letters he had received relating particularly to the conditions of the nursing staffs in hospitals and institutions. The first letter came from a national organisation of a responsible trade union catering for this class of worker. He said—

'Owing to the long hours, which are aggravated particularly by split duties, or spread-over system, a number of authorities are finding it almost impossible to

recruit adequate nursing staffs for their hospitals. In most recent case I know of in this connexion is that of the — county council, whose chief officer reported that it was unable to recruit the necessary number of nurses to staff their hospitals and institutions, and that in fact at the present time they are short staffed.'

The other quotation was from a lady member of a local authority. She said—

'The facts are that great difficulty is being experienced at the moment throughout the country in inducing women to enter institutional life owing to the prevailing conditions. With regard to the nurses a very acute shortage of entrants to the profession is being experienced especially by municipal hospitals. It would be true to say that a serious epidemic occurred in London or in one of the large provincial towns there would not be a sufficient staff to man the hospitals. The reasons given for this are long hours of duty spread over insufficient leisure time, and so on.'

Leave was granted to bring in the Bill, which was read a first time.

Mr CLEMENT DAVIES presented the Magdalen Hospital Bill a measure to confirm a scheme of the Charity Commissioners for the application of management of the charity called the Magdalen Hospital in the County of London. The Bill was read a first time.

INSANITY AS GROUND FOR DIVORCE

In the House of Commons on April 16th the Marriage Bill, as amended in Standing Committee was considered on Report.

Mr TURTON moved an amendment to make it grant of divorce on the grounds of incurable insanity subject to a period of seven years instead of five. That period, he said, would be more consistent with the present law and would also give a better safeguard to those who disliked giving divorce on the grounds.

Commander BOWER, in seconding the amendment said this was one of the most difficult questions to deal with. It was difficult to find any medical man who would give a definition of incurable insanity or would definitely say that the condition of a particular patient was incurable. This allowed of divorce for insanity, whether considered incurable or not, might in many cases have a most unfortunate effect on a patient of unstable mind. Most important of all was the question of those who had voluntarily entered a mental institution. A voluntary patient under Section 1 (5) of the Act of 1930 might leave the institution, hospital, or home on giving 72 hours' notice, or if he was under 16 such notice was given by parent or guardian. They therefore had an astonishing legal anomaly that a person who was well enough to go out of an institution at short notice under the Act was considered by the promoters of this Marriage Bill to be so insane that he could be divorced behind his back.

Sir J WITHERS. No. There is a period of five years and also there must be medical evidence.

Lieut Commander AGNEW said that not only was medical opinion confused but public opinion was in grave doubts on this question. When the doubts existed the period necessary for granting divorce for incurable insanity should not be less than for granting it for overseas desertion, which was provided for the presumption of death after five years.

Sir ARNOLD WILSON said that on behalf of the promoters of the Bill he opposed the amendment. The recommendation of the Royal Commission in 1912 on this subject was that five years should be the period during which continuous care and treatment should be applied before there could be judgment on the matter of incurability.

Mr CROSSLEY asked if the clause meant that a decision could be taken by any medical authority about the incurability of a patient until he had been in an institution for five years.

Sir A. WILSON said that was so. The conditions were that not only must the patient be continuously under treatment for five years but he must also after that be subjected to a medical examination which in the opinion of the Court was sufficient to prove that he was in fact incurably insane. Every thing that had been said in support of the amendment justified the conclusion that doctors would in future be increasingly reluctant to declare that a person was incurably of unsound mind and that the question of five years would be of less importance than it was in 1912. As to the voluntary patients he pointed out that they must have been continuously under treatment without any interval. After a very careful survey of the reports of the Board of Control of the last few years of the figures about incurability and of the very great efforts which were being made with the aid of funds provided by the Medical Research Council the Rockefeller Trust and others to extend the possible relief of insanity he was confident that this clause was as safe as anybody could make it and that they would be ill-advised to increase to seven years the period during which a patient must be under continuous treatment. Out of 100 possible recoveries only two took place after the period of five years.

After further debate the amendment was negatived by 111 votes to 48.

The further consideration of the Bill was adjourned.

NEW BLOCK GRANTS FOR SCOTLAND

In moving the second reading of the Local Government (Financial Provisions) (Scotland) Bill in the House of Commons on April 16th Mr. ELLIOT, Secretary of State for Scotland, said that the Bill had four main objects. First it fixed the amount of the Exchequer contribution given by way of block grant to Scottish local authorities for a period of five years. Secondly it relieved local authorities in Scotland of the payment of contributions under Section 45 of the Unemployment Act 1934. Thirdly it made provision for calculating the grant in future fixed grant periods; and lastly it amended the formula on the basis of which the larger part of the block grant was distributed among the local authorities. With regard to the amount of grant in the next five years the Bill proposed an annual sum of £2,827,000 per annum or £200,000 more than in the previous grant period. In addition it proposed to relieve local authorities of their liability to make payments towards the cost of unemployment assistance which amounted now to about £74,000 per annum. Furthermore no account was taken in arriving at this general Exchequer contribution of the relief afforded to county councils by the taking over of trunk roads which amounted to about £200,000 per annum. It would thus be seen that the local authorities in Scotland would be better off in the next fixed grant period to the extent of £1,433,000 a year than at the present time a very substantial sum. The new formula was more heavily weighted for unemployment and sparsity. The Bill would give substantial additional assistance to the parishes which stood in greatest need of it. The total additional relief amounted to nearly £1,500,000 and over £1,000,000 would be devoted to the necessitous areas. Substantial assistance would also be given to the less needy areas.

After further debate the Bill was read a second time.

MATERNITY SERVICES IN SCOTLAND

The Maternity Services (Scotland) Bill as amended in Standing Committee was considered on Report. Mr. LEONARD moved the following new clause—

It shall be lawful for a local authority in consultation with the local organisation of registered medical practitioners as referred to in sub-section (5) of Section 1 of the Act to publish annually a panel of registered medical practitioners for the purposes of Section 22 of the Midwives (Scotland) Act 1913 such panel to consist of registered medical practitioners regularly practising

midwifery and to be made available to all certified midwives practising within the area of the local authority.

He said the intention was really to give a lead to local authorities.

Mr. MATTHEWS in seconding the new clause said that it simply sought to put into the hands of practising midwives a list of medical practitioners who would be able effectively to assist them in any emergency that they might encounter.

Mr. ELLIOT, Secretary of State for Scotland, said he had every sympathy with the object of the new clause, but in the schemes under the Bill there would be full provision for the midwives to know where the practitioners and indeed the specialists were. The impression of his Department was that the scheme would cover 80 per cent of the confinements in Scotland. The other 20 per cent would not be the poor people but the well-to-do who had their own doctors and were in touch with the obstetric specialist as well. It would not be left to the midwives to pick a doctor from a casual list of practitioners which might or might not be issued by the local authorities. It would be the duty of the midwife to be in touch and to work with the woman's own medical attendant and if she did not know where the medical attendant was or where in his absence some other practitioner could be found then she would be in fault under the new schemes. He hoped the hon. Members who had put forward this new clause would consider that their purpose would be achieved in the schemes under the Bill and would not press the matter.

Mr. LEONARD said he was indebted to the Secretary of State for his explanation and was willing to withdraw the clause.

The clause was withdrawn.

Mr. ELLIOT moved an amendment to the clause providing that the medical schools and other midwifery training bodies should have an opportunity to make representations.

This amendment was agreed to.

Mr. WESTWOOD moved an amendment the purpose of which he said was to strengthen the prohibition of unqualified persons from acting. It was felt that under this clause it would be possible for a young medical student just entering on his studies or for a temporary nurse just starting her training to take control of a case. That was altogether unsatisfactory. Both student and nurse ought to be given a period of training of at least three years before having the responsibility of dealing with maternity cases.

Mr. ELLIOT said neither medical students nor pupil midwives could now undertake a domiciliary case until they had had a complete theoretical course and adequate practical instruction including the delivering of women in labour under qualified supervision in an institution. The existing safeguards went further than the statutory form suggested in the amendment. Under the rules of the General Medical Council no medical student might undertake practical midwifery until the last term of the fourth year of his curriculum. Further he would point out that the whole matter was governed by schemes and he undertook in scrutinising these schemes to give his personal attention to them and to ensure that no danger should arise of medical students going out to cases earlier than the period which hon. Members had put forward. He was certain that the General Medical Council had no intention of relaxing their rules and it might well be that their rules were stiff. He did not want to undertake that men should not go out under three years training when the General Medical Council said that they should not go out until the last term of their fourth year. He hoped the House would consider that his suggestion was adequate to deal with the question of the training of medical students.

Mr. WESTWOOD said after the explanation of the Secretary of State and the pledge he had given he was prepared to withdraw the amendment.

Mr WESTWOOD said the right hon gentleman's explanation on the training of the medical student was quite satisfactory but he thought the House was entitled to an explanation with regard to the training of the nurse. He moved an amendment that midwives should have at least two years' training.

Mr ELLIOT said the full course of the midwives curriculum under the rules of the Central Midwives Board extended over only twelve months and therefore he did not think the amendment would be possible in practice. The Central Midwives Board contemplated an extended period of training, but not, he thought, to the extent which would render this amendment practicable. Women who were already registered nurses under the Nurses Registration Act qualified as midwives after a six months' course, but being registered as nurses they had had a long training already. He thought Mr Westwood had more in view people who were working for the full course of the midwives curriculum under the Central Midwives Board. Looking at the matter from that point of view it would be difficult to start amending by Statute the rules of the Central Midwives Board. The Board tried to make sure that no one should be asked to undertake this tremendous responsibility without having gone through a course which the responsible professional people thought was a proper one. He would, however, be very glad to look into the question whether there was any loophole or gap by which comparatively untrained persons could be faced with this very great responsibility. His belief, however, was that that would not and could not arise. If any safeguard was necessary it could be secured in the schemes framed in conjunction with the local authority and subject to the approval of the Department.

Mr MAXTON said the Secretary of State was relying upon the appropriate professional organisations to see to this matter, but the evil they were trying to combat had grown up under existing professional organisations.

Mr ELLIOT said that the evil to which the hon Member referred had been combated and was in process of eradication under these professional bodies. He thought the professional bodies were tightening up their regulations almost every year in regard to these things.

Mr WESTWOOD said after the very clear explanation and promise given by the Secretary of State he was willing to withdraw the amendment.

The Report stage was concluded and the Bill was read the third time and passed.

THE BUDGET

HIGHER INCOME-TAX AND NEW TRADE PROFITS DUTY

In the House of Commons on April 20th Mr CHAMBERLAIN, Chancellor of the Exchequer, introduced his Budget. He said that in spite of an allowance of over £50,000,000 more for defence in his last Budget a small surplus was anticipated. Owing, however, to the recent acceleration of the defence programme there was an actual realised deficit of £5,597,000. If the defence expenditure had not exceeded the Budget provision by £7,821,000 there would have been a formal surplus of nearly £2,250,000 after applying over £13,000,000 of ordinary revenue to debt redemption. The total revenue for 1937-38 was estimated at £847,050,000 and the total expenditure at £862,848,000, leaving a deficit of £14,808,000.

Dealing with his proposals for changes in taxation the right hon. gentleman indicated that steps would be taken to deal with tax avoidance in regard to "bond washing" and one man investment companies. The report of the Select Committee on the Medicine Stamp Duties had been made public. He had had a good many representations from various quarters since the publication of the report and he was having the recommendations of the committee examined in the light of those representations. But in view of

the very complex issues involved and the extra strain upon the time of Parliament he was not proposing to introduce legislation on that subject in the Finance Bill this year. (Cheers)

Effect would be given from Jan 1st, 1938, to the recent announcement by the Minister of Health in regard to the abolition of the Male Servant Licence Duty. The rate of income-tax would be raised by 3d in the £ to 5s and there would be a new graduated duty on the growth of profits of trades and businesses called the "National Defence Contribution." Mr Chamberlain made it clear that professional would be exempt from the new tax. The additional 3d in the £ on income-tax, the new profits duty and the measures to deal with tax avoidance were expected to yield an additional revenue of £15,150,000 this year, making a total estimated revenue of £863,100,000. After taking account of a total estimated expenditure of £862,848,000 there was an anticipated surplus of £252,000. The aim of his Budget, said Mr Chamberlain, was on the one hand to avoid a tremendous increase in tax burdens which would check convalescence—hence the decision to resort to borrowing for defence purposes—and on the other hand to make such increases as would check feverish activity without inspiring an upstart trend.

In the House of Lords on April 15th the Education (Deaf Children) Bill was read the third time and passed.

In the House of Commons on April 16th the Methylated Spirits (Scotland) Bill was read the third time and passed.

QUESTION TIME

WEDNESDAY, APRIL 14TH

Human Nutrition in Tanganyika

Mr MATHERS asked the Secretary of State for the Colonies whether he could make any statement as to the departmental committee in Tanganyika on the subject of human nutrition in that territory, and whether the committee would take into consideration the work by the International Institute of African Languages and Cultures, pointing out the need of combining medical and anthropological inquiry in respect of nutrition problems.—Mr ORMSBY GORE replied. As the result of the circular dispatch published in 1936 as Colonial No. 121, a Departmental Committee has been set up in Tanganyika as in many other parts of the Colonial Empire to study questions relating to human nutrition. Copies of the memorandum to which the hon Member has already been sent to all African Governments. I have no doubt that the desirability of combining medical and anthropological inquiry will be given full weight to the Committee.

Mr MATHERS: Is there any actual guidance in the dispatch referred to that inquiry should follow the lines?—Mr ORMSBY GORE: Yes. This dispatch suggests certain lines and I think the hon Member knows a special Committee of the Civil and Research Organisation is receiving replies as they come in from the various Dependencies.

Unemployment and Sterilisation in Bermuda

Mr GALLAGHER asked the Secretary of State for the Colonies whether his attention had been drawn to the recommendations contained in the report of the Committee appointed on Feb 5th, 1935, to consider a report on the existing state of unemployment in Bermuda if he was aware that these recommendations provided compulsory sterilisation, whether it was proposed to give effect to these recommendations by means of legislation and if so, whether he would intimate to the Government of Bermuda that the recommendations of the Select Committee were objectionable and that the proposed legislation should not be proceeded with.—Mr ORMSBY GORE replied. The answer to the first and second parts of the question is in the affirmative. As regards the latter part of the question I am informed by the Govern-

of Bermuda that no action regarding compulsory sterilisation is contemplated.

THURSDAY APRIL 16TH

Labour Exchange and Manchester Royal Infirmary

Mr FLEMING asked the Minister of Labour whether he had considered the objection submitted to him against his proposal to erect a labour exchange adjoining the central branch of the Manchester Royal Infirmary; and whether he still intended to proceed with the said building—Mr ELLIS SMITH Mr WEDGWOOD BENN and Mr EMBAY asked similar questions on the same subject—Mr EMBAY Brown replied: I am now in consultation with the Joint Commissioner of Works regarding certain proposals recently made to me informally on behalf of the Board of the Manchester Royal Infirmary but until our inquiries are completed I am unable to make any statement.

Mr FLEMING Has the Minister considered the serious objection of the medical profession in Manchester on the ground that this proposed building will gravely obstruct the work that is being carried on in the central branch of the Royal Infirmary?—Mr Brown: I am aware not only of that objection but of some others which have been put to me. I am also aware that for 15 years past the great social service of the Employment Exchange in Manchester has been carried on in a building that is utterly unsuitable and not fair to the staff concerned. Mr BENN: Has the right hon. gentleman taken any advice as to the public opinion in Manchester with regard to this matter? If not will he be good enough to do so? Mr Brown: I am well aware of the opinion in Manchester. At the request of the representative of the Infirmary I saw him privately and it is for that reason that I am now doing my best to carry out the promise I made to him that I would get consideration for this matter. Replying further to Mr Benn Mr Brown said that some time ago he saw a very important body on this matter and heard all the arguments over again. Mr E SMITH: Would the right hon. gentleman also consider the alternative of taking into consultation the Office of Works with a view to taking over the site and suitably compensating the Manchester Royal Infirmary?

Mr Brown: I prefer to make no statement about that for the moment.

Hours of Employment of Young Persons

Mr PALING asked the Home Secretary whether the Government had considered the report of the Departmental Committee on the hours of employment of young persons in certain unregulated occupations; and what steps they proposed to take—Sir JOHN SIMON replied: Sir, I have been giving careful consideration to this important report and I am hopeful that it will be possible to deal in the Factories Bill with the hours of the young persons employed in connexion with factories, docks and warehouses whose inclusion in the new factory code is recommended by the Committee. As regards the other classes of young persons in whose case the Committee suggested an extension of the Shops Act 1934 it would be necessary to introduce separate legislation which could not be undertaken during the present session.

Deaths following Vaccination

Mr GROSS asked the Minister of Health the number of deaths of infants due to vaccination recorded by the Registrar General in the last ten years—Sir KENNEDY GODDARD replied: The number of deaths of infants under one year of age classified to vaccination or other sequelae of vaccination during the ten years 1926 to 1935 was 4.

MONDAY APRIL 19TH

Medical Practitioners in Nigeria

Lieut. Commander FLETCHER asked the Secretary of State for the Colonies the number of medical practitioners in Nigeria and the proportion born by this number to the total population—Mr OWENSON GORE replied: The number of registered medical practitioners in Nigeria including Mandated Territory on Jan. 1st 1937 was 224. This number bears to the total population a proportion of one medical practitioner to every 80,500 persons approximately.

TUESDAY APRIL 20TH

Insurance Committees and Physical Training

Mr KENNEDY asked the Secretary of State for Scotland if he had considered a resolution adopted and sent to him by the Kirkcaldy Insurance Committee complaining that no representative of national health insurance committees was included in the list of members who were to be responsible for the organisation of the work of the National Advisory Council for Physical Training and Recreation for Scotland and if this omission could now be rectified—Mr ELLIOT replied: The answer to the first part of the question is in the affirmative. With regard to the second part the members of the Council were appointed because of their personal qualifications and not as representatives of particular organisations. It is not at present proposed to add to their number but in the event of further appointments being made the possibility of adding a member with special knowledge of national health insurance work will be kept in view.

Ex Service Man and Treatment for Tuberculosis

Mr GEORGE GRIFFITHS asked the Secretary of State for War whether he was aware that D. A. Warham No. 6 012 364 was discharged from the Rifle Brigade suffering from tuberculosis, that there was no trace of tuberculosis in the soldier's family; if he received any treatment for the disease and whether the man received a pension or a gratuity—Mr DUFF COOPER replied: Yes, Sir. Mr Warham's case received thorough investigation and treatment including surgical treatment which effected a considerable improvement in his condition. He received a gratuity of £18 on his discharge from the Army. I regret that as his disability was not caused by his service he is not eligible for a pension.

LCC HOSPITAL BUDGET

UNDER this heading on March 27th we published a statement of estimated expenditure by the London County Council on their general and special hospitals during 1937-38. It has been pointed out to us that the figures we reproduced relate only to votes on account pending the Council's approval of the complete votes for the year. We now publish the correct figures as submitted to the Council on Tuesday last.

The estimated capital expenditure on general and special hospitals during 1937-38 (excluding provisional sums) is £551,000. The estimated expenditure on maintenance is £5,743,605 made up as follows—

General hospitals	£ 3,398,750
Infectious hospitals	912,460
Sanatoria	217,934
Children's hospitals	3,205
Pathological laboratories	61,63
Maintenance in hospital other than the	
provided by the Council, &c.	203,070
District medical service	41,075
London ambulance service	170,095
Staff	154,095
Miscellaneous expenses	17,495
Sanitary officers	9,261
Public vaccinators	1,000
Diagnosis and treatment of venereal diseases	11,100
Maternity and child welfare	57,600
Mildew services	4,700
Other public health services	945

The total net estimated expenditure for the year (£5,305,820) exceeds the net estimated expenditure for 1936-37 by £212,070. The two principal items accounting for the increase being about £12,000 additional expenditure on staff and about £78,000 extra under the heading of "provisions: clothing, drugs, domestic renewals, &c."

The estimates put forward by the mental hospital committee are £3,000 for capital expenditure and £2,708,425 for maintenance.

MEDICAL NEWS

University of Cambridge

The title of the M B degree has recently been conferred on Mrs E M P Wilson

University of London

On May 3rd, 4th, and 5th, at 5 P M, at University College, Gower street, W C, Prof H Reim, director of the physiological institute in the University of Göttingen, will lecture on some economising mechanisms as a condition of the body's adaptation to increased activity. Later in the month four lectures on the history of physiology will also be given at University College on May 18th Mr E S Russell, D Sc, will speak on ancient biological conceptions, on May 20th and 21st Prof Charles Singer will speak on the emergence of modern physiological doctrines on May 24th Mr D McKie, D Sc, will speak on the development of theories regarding combustion and respiration in the eighteenth century, and on May 25th Mr F G Young Ph D, will speak on the development of certain aspects of metabolism during the nineteenth century. These lectures will be at 5.30 P M. The lectures are open to all interested.

University of Aberdeen

A capital sum has been given anonymously to the university for the foundation of a part time lectureship in psychopathology. It is a condition of the gift that the lecturer shall not be an alienist and that his clinical work shall be done at the Royal Infirmary. The sum of £500 has also been received from Lord Glanely to permit research in rheumatism.

Royal College of Surgeons of England

The museum of the college will be open at the usual times on and after Monday, April 26th.

Royal College of Physicians of Edinburgh

The council of the college will shortly award a Kirk Duncanson fellowship for medical research. Its value will be £300 for the first year. Further information may be had from the secretary of the college, to whom applications should be sent not later than June 30th.

Aberdeen University Club, London

The ninety seventh half yearly dinner of this club will be held at the Café Royal Regent-street, at 7.30 P M on Thursday, April 29th. The chairman will be Sir Peter Chalmers Mitchell, F R S, and the chief guest Sir Benjamin Robertson. The hon secretary's address is 51, Harley street, W 1.

Child Guidance Council

Three fellowships in psychiatry, each of the value of £300, are offered for half time work at the London Child Guidance Clinic 1, Canonbury place, N 1. Further information may be had from the secretary of the council, Woburn House, Upper Woburn place, London, W C 1, and the closing date for receiving applications is May 10th.

Indian Medical Service

The annual dinner of the Indian Medical Service will be held at the Trocadero Restaurant, London on Wednesday June 16th, at 7.15 P M, when Sir Rickard Christophers F R S, will preside. Tickets may be obtained from the joint hon secretary Sir Thomas Carey Evans Hammersmith Hospital, L C C, Ducane road, London, W 12.

The Red Cross in Spain

The international committee of the Red Cross reports that its appeal for funds and for gifts in kind for the relief of the victims of the civil war in Spain continues to meet with response from Red Cross Societies in all parts of the world but that considerably larger sums are required to meet the appalling needs. The committee continues to pay special attention to the question of help to prisoners. Visits to prisons by Red Cross representatives are now permitted in many localities and standardised parcels of food and clothing are distributed. Prison hospitals have been established and some prisoners have been exchanged. Contributions may be addressed to Sir Arthur Stanley at 14, Grosvenor crescent, London, S W 1.

Royal Sanitary Institute

A meeting of this institute will be held in the B. Hall, Monmouth on Friday, May 7th, when Dr W P Nash, medical officer of health for Caerphilly, and Dr William Panes, assistant medical officer of health for Monmouthshire will open a discussion on immunisation in diphtheria. Mr J Jenkin Evans, sanitary inspector for Monmouthshire, will also open a discussion on the public health acts, and their implications in rural areas.

Institute of British Surgical Technicians

On Friday, April 30th, at 8 P M, at the Welbeck Hotel, Welbeck street, London, W, Sir Weldon Dalrymple Champneys will give a lecture to this society on the sterilisation of surgical ligatures. Tickets may be obtained free on application to the secretary of the institute, 6, Holborn Viaduct, London, E C 1.

Carey Coombs Memorial

The Carey Coombs memorial committee and the Bristol Medico Chirurgical Society have arranged for Mr Laurence O Shaughnessy to deliver a lecture on the operative treatment of cardiac ischaemia on Wednesday, May 22 at 8.30 P M in the physiological lecture theatre of the University of Bristol.

French Hospital, London

A clinic for the treatment of hay fever and allied conditions by ionisation is being opened at this hospital. The treatment, which is free, is available to all who speak French irrespective of creed or nationality, and will be given on Wednesdays at 4 P M (first attendance Thursday at 2 P M). Further information may be had from the secretary of the hospital, Shaftesbury avenue, London, W 1.

Institute of Ray Therapy

This institute was established in 1930 at 152, Camden road, London, N W. Its object is "to provide every form of electrical treatment for people of small means" whom it would not otherwise be obtainable" and it is open daily from 2 P M to 9 P M. During 1936 no less than 106,460 treatments were given, and an appeal is now being launched for £25,000 to increase the equipment and enlarge the building. At a luncheon held on Monday Lord Horder the president said that the work done at the institute was now well known to doctors in the neighbourhood and also outside it. In many conditions physical methods had largely superseded the use of medicine in which patients had so much faith, but physiotherapy could not be very satisfactorily undertaken outside a clinic or an institution which provided up-to-date equipment and nursing facilities and men and women with expert training. The public needed a warning against indiscriminate use of old-fashioned machines by untrained people, which was really a form of quackery. Lord Sempill, chairman of the board of governors, explained that unless £25,000 could be obtained at the end of this year, the work being done at the institute would have to be curtailed and patients turned away. At general hospitals surgical and medical work had to take precedence of electrical treatment, and whenever space was urgently needed in a general hospital the electrotherapy department was crowded out—partly because it needed considerable floor space and a special staff. The conditions treated at the institute included rheumatism and kindred diseases, accident cases, discharge from hospital, children's diseases such as rickets, adolescent rheumatism, and enlarged glands, skin diseases, nervous disorders, and diseases of the nose and throat. The institute could and should be a great centre of physical medicine in Great Britain, to compare with the most modern and efficient in Europe and America. It had grown, like all great movements from a very small beginning but it had grown continuously in usefulness.

Other speakers at the luncheon included Miss F. Vanbrugh and Mr Russell Howard who is a member of the medical advisory committee. The honorary physician and medical director is Dr William Beaumont.

Maternity Centre at Loughborough

A new maternity and child welfare centre has been opened here by the mayor to mark the twenty first year of infant welfare work in the town.

Joint Tuberculosis Council

A series of intensive post-graduate courses are being given under the auspices of this council by Dr. Peter Edwards at Cheadle Joint Sanatorium near Market Drayton. The subject is modern methods of therapy in tuberculosis of the respiratory system with special reference to collapse therapy. The next course will be held from May 25th to 27th and there will also be courses from Oct. 28th to 30th and from Nov. 23rd to 25th. Further information may be had from Dr. William Brand, the council's hon. secretary for post-graduate courses, 8 Christ Church place, Epsom, Surrey.

Society for the Relief of Widows and Orphans of Medical Men

A quarterly court of the directors of this society was held on April 7th. The deaths of three of the members were reported and five new members were elected. It was announced that a donation of £111 had been received from the Royal Medical Agency. A first application for relief was received from a widow of a member who was awarded a yearly grant of £50 from the ordinary funds and £25 from the Brickwell fund. The number of widows at the present time in receipt of relief has now reached a total of 60 which is the largest number to be dependent on the society at any one time. The annual general meeting of the society will be held on Wednesday, May 10th at 5 p.m. Membership of the society is open to any registered medical man who at the time of his decease is resident within a twenty mile radius of Charing Cross. Full particulars may be obtained from the secretary, the offices of the society, 11 Chandos street, London, W.1.

International Congress of Radiology

The fifth International Congress of Radiology will meet in Chicago from Sept. 13th to 17th under the presidency of Dr. Arthur C. Christie (Washington). The international executive committee of the congress includes Dr. C. Hurston Holland (Liverpool), Dr. Gösta Forszell (Stockholm), Dr. Antoine Béchère (Paris), Dr. Hans R. Schinz (Zürich), Dr. Karl Frik (Berlin), Dr. Mario Ponzio (Turin), Tamotsu Watanabe (Osaka), Dr. Heliodoro Tellez (Santiago), and Dr. Gottwald Schwarz (Vienna). Russell Reynolds is chairman of the British national group and may be addressed at 30 Harley-street, London. More than 250 scientific papers will be read at the 5-day meeting; they will be delivered in the lecturer's own language and will be flashed on screens simultaneously in English, German, and French as the papers are read. Scientific and technical exhibition will also be held. The secretary of the congress is Dr. B. H. Orndoff, 2601 Clark street, Chicago.

Extended District Nursing Scheme for London

At a meeting held on April 18th under the chairmanship of the Earl of Athlone it was recalled how Florence Nightingale in a letter to the *Times* on April 14th, 1876, noted an old woman who said: "They nurses is real things; now husbands and fathers did ought to pay a niny per week as ud give us a right to call upon they nices when we wants them." Miss Nightingale thought the old woman had put forward a sensible plan and it was the purpose of this meeting held almost exactly 60 years later to put it into practice by instituting a Greater London provident scheme for district nursing. It is hoped wherever there are five or more people regularly employed to make it possible for them to subscribe to the nursing service at the rate of a halfpenny a week. They are not earning more than £8 a week. The benefits will include free nursing care, subject to medical direction, the patient's home for contributors and their dependents, a loan of certain nursing appliances, Midwives' small maternity ward and certain infectious diseases excluded. Lord Horder and Miss Mary Wilmshurst, medical superintendent of the Queen's Institute of District Nursing were among the speakers who supported the scheme. The executive committee may be addressed at Sloane street, S.W.1.

Papworth Village Settlement

At the festival dinner of this settlement on April 20th over which the Duke of Kent presided it was announced that a sufficient sum had been raised to claim Lord Nuffield's provisional gift of £25,000. Mr. E. W. Meyerstein has also given £20,000 towards building the new nurses' home.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Capt. P. L. Gibson to *President* for course.
Surg. Capt. C. F. O. Sankoy O.B.L. to *Victory* for R.N. Hosp. Haslar. W. H. Edgar O.B.E. to *Victory* for R.N.B. and E. Moxon Browne to *Queen Elizabeth*.
Surg. Lt. Comdr. F. Dolan to *Drake* for R.N.B. and to *Colombo* and J. L. Malone to *Pembroke* for R.N.B.
Surg. Lts. I. C. Macdonald to *Pembroke* for R.M. Infirmary Deal; H. O. Connor to *Arrow*. W. H. C. M. Hamilton to *Falcon*. T. A. M. Mansell to *President* for course and to *Drake* for R.N.B. F. A. Croxall to *London*. R. V. Jones to *Challenger*. L. R. Norworthy and G. R. Rhodes to *Drake* for R.N.B. B. O'Neill and M. G. Ross to *Pembroke* for R.N.B. P. G. Stainton to *Victory* for R.N. Hosp. Haslar. F. P. Ellis to *Pembroke* for R.N. Hosp. Chatham; W. S. Miller to *Shropshire*. A. J. Glazebrook to *Excellent* and to *Tedworth* (on commg.); J. G. Vincent Smith to *Victory* for R.N.B.; G. H. C. Critien to *Drake* and W. Boyd to *Cairo*.
The entry of W. G. Smith L.D.S. as Surg. Lt. (D) (published in the *Gazette* of April 2nd) is cancelled. (Vide *Lancet* April 10th.)

ARMY MEDICAL SERVICES

Maj. Gen. FitzG. G. FitzGerald C.B. D.S.O. h.H.S. late R.A.M.C. h.p. retires on ret. pay. Col. A. F. S. Irvine D.S.O. late R.A.M.C. having attained the age for retirement is placed on ret. pay. Lt.-Col. S. W. Kyle from R.A.M.C. to be Col.; Maj. Gen. H. H. A. Emerson, D.S.O. late R.A.M.C. is appointed Hon. Surg. to the King. Vice Maj. Gen. FitzG. G. FitzGerald.

ROYAL ARMY MEDICAL CORPS

Maj. F. S. Gillespie to be Lt. Col.
Maj. R. J. Rosie is retired to the estate.

TERRITORIAL ARMY

Capt. D. S. Middleton to be Maj.
Capt. J. J. McNery resigns his commission.

TERRITORIAL ARMY RESERVE OF OFFICERS

Capt. C. A. D. Mitchell from Active List to be Capt.

ROYAL AIR FORCE

Wing Comdr. R. S. Overton to R.A.F. Depot Uxbridge for duty as Medical Officer.
Flight Lt. R. L. Alderson to R.A.F. General Hospital Palestine and Transjordan Sarafand; R. A. Cunningham to No. 203 (Flying Boat) Squadron Basrah Iraq; and J. R. Collins to R.A.F. Station Amman Palestine.
Flying Offr. A. R. Silbald is transferred to the Reserve class D.
Flying Offr. J. Conroy resigns his short service commission.
Flying Offr. J. H. Lewis to No. 2 Flying Training School Digby; S. Iaul to No. 7 Flying Training School Peterborough; and E. B. Sidney to No. 1 Flying Training School, Leuchars.
Dental Branch—Flying Offrs. promoted to rank of Flight Lt.: I. St. C. Aldercliffe O.F. Brown J. H. G. Fensom R. Hill R. A. Pepper and W. H. Smith.

INDIAN MEDICAL SERVICE

Capt. K. M. Bharucha to be Maj.
Indian Medical Department—The unmentioned officers retire. Maj. (Sen. Asst. Surg.) J. B. V. Bracanza and P. H. Foy; Lt. (Sen. Asst. Surg.) J. G. Johnstone G.R.C. on account of ill health.

BIRMINGHAM HOSPITALS CONTRIBUTORY ASSOCIATION—During the nine years of its existence this association has collected and distributed £2,750 984 and its income has risen from £150 000 to £381 000 while expenses do not exceed about 5 per cent. There are about half a million contributors.

nerics.—The Danish and Swedish national groups of the International General Medical Association for Psychotropic Remedies are arranging for the ninth international congress to be held at Copenhagen from Oct. 2nd to 4th. On the first day the subject for discussion will be psychotherapeutics and general practice, on the second the teachability of psychotherapeutics, while the third day will be reserved for other papers, discussions and general business. Papers may be read in German, English or French, and anyone who wishes to read one should notify the president of the association Prof O G Jung, Kusanact, Zürich, before June 1st. The congress is open to all medical men; other psychotherapists and practical psychologists may also take part at the invitation of the various national groups. Dr Oluf Brülé, 2, Amagervej, Copenhagen is secretary for the Danish group and Prof Paul Bjerré, 4 Långbrokrysatan Stockholm for the Swedish group.

NOTES, COMMENTS, AND ABSTRACTS

MEDICINE IN THE PHYSICAL LABORATORY

ONE of the primary concerns of the National Physical Laboratory is to give to industry the scientific help it needs. The annual report for 1936 shows how much of its work has been directed to that end. Many of the investigations, however, are directly related to public health and medicine. One important piece of work has resulted in the unification of X ray and radium dosage measurements, a difficulty of deep radiation therapy has been the correlation of the dosage of these two kinds of radiation. During the year two methods, one using ionisation chambers, the other photography, have been worked out so that radiation from the two sources may be measured in terms of the roentgen, the international unit. Another difficulty, arising from the increasing power of X ray therapy installations, has been the protection of the medical observer from stray radiation. An optical system which was first studied because of its innate interest has been found to provide means of viewing the patient while he is separated from the observer by a thick protective wall.

X rays have been used for studying dental structure. The main crystalline constituent of the enamel proves to be identical with that of dentine, but while the crystallites in the dentine are orientated at random, there is a fibre structure in the enamel. This structure is developed to a greater or less degree in different enamels, a high-quality enamel being associated, generally speaking, with a well marked fibre structure. It appears that calcification is more conspicuous in the enamel the later the enamel is formed in the life of the tooth.

The attack upon noise has been made on several fronts. Loudness is essentially a subjective characteristic of sound and the measurement of it, except by direct comparison, has been unreliable in the past. An objective meter which gives dial readings corresponding to aural loudness has now been designed and tested at the laboratory. It is free from all suspicion of personal error and bias and has the great advantage that it registers the loudness of intermittent and impulsive noises which are so often the cause for complaint. The meter has been used to measure the noisiness of cars, lorries, buses, and motor bicycles. Measurements have also been made for the Home Office of instruments which might be used as alarm signals in air-raids, and of road drills. The silencing capacity of different kinds of floors and partitions has been measured for the Ministry of Health in connexion with the construction of flats for the working classes.

During the winter 1935-36 observations were made to determine the value of daylight illumination at which clerical workers find it necessary to turn on artificial light. The laboratory, in co-operation with H. V. Office of Works, arranged that seventeen typists in one of the large typing offices in Whitehall should have their lights fitted with a device which, unknown to them, recorded the time at which each light was switched on and the illumination at the working position at the instant of switching on. Although the results showed a considerable spread, on average the light was turned on when the daylight had fallen to a value of about 5 foot-candles. Another instrument for measuring daylight has been devised for use more particularly in deep rooms or rooms badly provided with daylight, it should be of service to public health departments having slum clearance schemes. The researches on illumination problems have also been directed to the subject of glare.

The report mentions that the laboratory maintains equipment for testing the distribution of radiation in limited spectral regions from sources such as those much used in therapy recently. On the other hand, many glasses have been examined for the protection they afford to radiation of different

parts of the spectrum. Most of those against ultraviolet light were found to be satisfactory, but many of those designed to satisfy the conditions laid down for infra-red radiation failed by a large margin. It is therefore probable that large numbers of industrial workers are deriving from their protective goggles much less protection than is believed desirable and less than is certainly obtainable without sacrifice in the visibility of the work.

Among the routine undertakings of the laboratory are the assaying of radium and the testing of clinical thermometers, the latter must now be of a certain thickness, have durable pigment on the scale, and have other fixed characteristics if they are to conform to the British standard specification and to receive the "Kew" certificate.

CONVALESCENT HOMES FOR CHILDREN WITH RHEUMATIC CARDITIS

THE value of convalescent establishments for children suffering from rheumatic carditis has been much debated. It is pleasant to learn therefore from the annual report for 1936 of the Children's Heart Home, Lancing, Sussex, that the results of treatment at this home have been good. Its members of the honorary staff of the Hospital for Sick Children, Great Ormond-street, are consulting physicians to the home at Lancing, which accommodates 70 children and provides them with education satisfying the Board of Education. The average length of stay of each child in 1936 was 100 days (a period considerably shorter than that reported at Birmingham and Broadstairs 10 years ago), preponderance of girls over boys was 140 to 1 and the ages of the children received between 5 and 12. Otherwise the report includes no clinical details. During the last 10 years so many new beds have been set aside for the treatment of rheumatic disease in childhood, that it is clear that sufficient material must have accumulated for the publication of the results of treatment, and, even more important, treatment plus after care and of re-examination of children returned to their homes. Ten years' relapse after return home in some form (rheumatic carditis, or chorea) occurred in about one-third of children re-examined, and it is of cardinal importance to know whether these figures have importance. The cases under treatment at West Wycombe, Lancing, and in even greater numbers at Cardiac and Brentwood under the L.C.C. should by this time be adequate to furnish the basis of a comprehensive report which would be welcomed by all interested in the problem presented by rheumatic carditis.

BOARD OF CONTROL.—The Board of Control, under the approval of the Minister of Health, have appointed a committee to advise upon questions arising in connexion with scientific and ancillary mental health services which will include the following: Lord P. (chairman) Sir Laurence Brock, Sir Hubert Bond, A. A. W. Petrie, Dr. Adelino Roberts, Dr. C. Thomas, and Dr. George Somerville. Mr. H. J. G. will act as secretary. The Mental Treatment Act, 1930, empowered local authorities to provide for patient treatment and for the after care of mental patients, and, subject to the approval of the Board, to undertake or contribute towards the expenses of, research in relation to mental illness. An advisory committee was appointed in 1931 but owing to the financial crisis its work fell into abeyance. The primary function of the new committee will be to advise the Board on the organisation and encouragement of research, and other ancillary matters, will be within its purview. On technical questions relating to research the committee will have the expert advice of members of the committee on mental disorders of the Medical Research Council.

ADDRESSES AND ORIGINAL ARTICLES

THE PREVENTION OF PULMONARY TUBERCULOSIS AMONG ADULTS IN ENGLAND IN THE PAST AND IN THE FUTURE *

BY P. M. D. ARCT HART, M.D. Camb. F.R.C.P. Lond.

ASSISTANT PHYSICIAN TO UNIVERSITY COLLEGE
HOSPITAL, LONDON

(Continued from p. 973)

THE national tuberculosis scheme was designed at a time when contact with open tuberculosis was considered chiefly dangerous to children. While precautions were advised for adults, doubts as to their necessity were commonly expressed. During the last decade or so however more attention has been paid to the risks run by adults and particularly by young adults. This is evident from the opinions of many physicians to the London tuberculosis dispensaries (noted by Bentley (1936)) who points out also that the incidence of new pulmonary cases in London during 1926-35 among child contacts examined was 10 per cent whereas among adult contacts examined was 7 per cent.

It is obvious that exposure in some form is more dangerous than no exposure at all for without exposure there can be no infection but we should like to know the position of adults facing exceptional exposure to contact as compared with that of adults encountering exposures of the kind met with in ordinary life. Again we should like to know whether young adults run a greater risk from exposures than older persons; and to know the part played by exposure incurred before adult life in the development of progressive lesions later, compared with the effect of exposure encountered actually during adult life. And we should also like to know the comparative risks run by adults who react negatively and those who react positively to tuberculin.

What information is available? Of late years much work has been published upon the fate of adults who are facing or are about to face exceptional amounts of exposure. Among these are home contacts, work contacts, medical students, and

were of the "adult" type. In exposed children the radiographic incidence of primary lung complexes increased with the length of time after the commencement of the exposure but in these adults it did not and from this it was inferred that their adult type lesions were due to exogenous reinfection acquired by contact after the age of 15 in lungs already the site of first infection (see Opie, McPhedran and Putnam 1933, Putnam 1936). Since however the tuberculin reactions before the commencement of known exposure are unknown we cannot exclude the less likely hypothesis that the adult type lesions found were due to endogenous reinfection (arising by blood spread) from a first infection focus that itself was acquired by contact after the age of 15. For while the proportion of persons that acquired first infection during exposure after the age of 15 might have been too small to cause a significant gradual increase in the radiographic incidence of primary complexes, it might still have sufficed to provide the number of adult-type lesions found.

It is clear at least from these valuable observations that exposure in their homes during adult life was an important factor in the production of adult type progressive pulmonary lesions in these contacts. And more recently these authors have brought forward evidence of the greater danger of this household contact to adults than to children (Opie, McPhedran and Putnam 1936).

Opie's procedure was in the main to identify his families by the primary case and to work forwards from the commencement of known contact. The opposite though more limited method has been used by Lloyd and MacPherson (1936) at the Brompton Hospital. They studied the case records of a series of clinically tuberculous young adults aged 15-24 so as to determine the time relationships with the termination of known exposure to any earlier case in the home or elsewhere. In 40 per cent of the patients evidence was found of such an earlier case the majority (82 per cent) having been in the home. In 80 per cent of the young adult patients with evidence of an earlier primary case the onset of their own disease was found to have been either while they were still in contact with the primary case or within five years of termination of known contact.

This work supports the view that home exposure to clinically recognisable tuberculosis during adolescence or adult life plays a large part in producing tuberculosis among young adults.

THE POSITION OF MEDICAL STUDENTS

The incidence and extent of radiographic adult type lesions in medical students appears to be greater during their clinical than their preclinical training. Since the students are older during the clinical course and since the morbidity of pulmonary tuberculosis also increases somewhat rapidly with age among young adults, assessment of the importance of contact depends almost entirely upon comparison with controls of the same age which are very difficult to obtain. However comparing medical students with a small series of dental and law students (Hetherington, McPhedran, Landis and Opie (1933)) did find a higher incidence of important adult type apical lesions in the medical students suggesting damage from exposure to contact in adult life during their clinical training.

THE POSITION OF HOSPITAL SURFACES: INFLUENCE OF PREVIOUS TUBERCULIN SENSITIVITY

The position of adult contacts has so far been discussed without reference to previous tuberculin

Adults Exposed to Exceptional Degrees of Contact

HOME CONTACTS

Using their comprehensive scheme of family records, Opie and his co-workers have studied the development of pulmonary tuberculosis in persons of various ages after exposure to contact with this disease in their homes in Philadelphia.

Persons apparently first exposed to sputum positive cases at some date after the age of 15 developed progressive lesions more often than persons similarly exposed to sputum negative cases and still more often than persons exposed to corresponding age in the general population. The annual attack rate of manifest—i.e. clinical—pulmonary tuberculosis in the persons exposed to sputum positive cases, showed this excess at its maximum 4-6 years after the commencement of the known exposure while their rate of death rate showed its maximum excess 2 years later.

With few exceptions these progressive pulmonary lesions in persons apparently first exposed after the age of 15

The Miltroy lectures for 1937 delivered before the Royal College of Physicians of London on Feb. 10th and 22nd 1931.

reactivity This aspect of the problem has been investigated in probationer nurses, a fair proportion of whom come direct from rural districts which means that many may be negative reactors on entry Heimbeck, working at Ullevaal Municipal Hospital, Oslo, found that tuberculin negative probationers, brought into contact with open tuberculosis during their training, ran a serious risk of developing lesions such as pleurisy, erythema nodosum, and even meningitis, attributable to tuberculous first infection These lesions, as might be expected, did not occur so often among those already first infected, as shown by a positive tuberculin reaction Hence the original "negatives" were at a disadvantage

Heimbeck's figures also appear to show that in a given limited time the original negative reactors developed serious adult type lesions more frequently than did the original positives These lesions might be explained as due to endogenous reinfection arising by blood spread from a first-infection focus acquired, by contact, during their training Heimbeck does not discuss this satisfactorily, but he does make it clear that he attributes this second difference between the fate of the originally negative but now positive nurses, and that of the originally positive nurses, to the previous possession of specific immunity by the latter but not by the former Hence the original negatives appear again to have been at a disadvantage He supports his view by citing the fate of nurses who became tuberculin positive as the result of BCG immunisation This was much the same as the fate of those who were originally positive without artificial immunisation

It should be noted that the cases of manifest disease described by Heimbeck among the originally tuberculin negative nurses of his series occurred within a year of their becoming positive, the latter change having usually taken place by the third year of their training, but for those who had not manifested the disease within one year of the change from negative to positive the subsequent fate was no different from that of the originally positive reactors (see Heimbeck 1936)

The appearance of troublesome accompaniments to tuberculous first infection in nurses who are negative reactors to tuberculin before their training, as found by Heimbeck, has been confirmed by several authors One of these (Mariette 1936) has also provided tentative confirmation of the greater risk of the adult type of disease appearing in this group than in the group of originally positive reactors This second difference in fate is, however, in conflict with Opie's experience with medical students, among whom no correspondence was found between the occurrence of adult-type lesions and the original tuberculin reactivity, nor does it agree well with Opie's interpretation of the adult-type lesions in his home contact series as being due to exogenous reinfection (see above) No final conclusion, therefore, can be reached until more information is available

A somewhat obvious suggestion as to the arrangement of the results of work on this problem may be made here It is best to compare the fate, in a given period, of the originally positive reactors not with that of all the originally negative reactors, but with the fate of those originally negative reactors who have become positive as a result of exposure In Heimbeck's work this would make no difference to the figures, since all his negative reactors changed to positive within three years of commencing exposure during their nursing training but, since such a change of reactivity does not take place so completely in all hospitals, the two above methods of comparison are not necessarily identical

Protection of Young Adults Exposed to Exceptional Degrees of Contact

The following three principles might reasonably be adopted for averting the possible danger to adults, who are, or are about to be, subjected to known or perhaps intense or frequent exposure to open tuberculosis

(1) Known exposure to contact in adult life, both tuberculin positive and of tuberculin negative persons should be reduced to a minimum. (In the near future this opinion may have to be modified to lay special stress upon young adults, and especially on negatively reacting young adults)

(2) Adults, both tuberculin positive and tuberculin negative, who are known to be in contact with open tuberculosis should be kept under observation during the period of exposure (This opinion also may have to be modified to lay special stress upon young adults and especially young adults whose tuberculin reaction is known to have changed from negative to positive as a result of the exposure)

(3) After the termination of the known exposure, the observation of adults (except perhaps those who have retained their negative reactivity) should be continued for some years

How can these principles be embodied in practice in the near future? The following remarks are restricted to young adults in the category under consideration—namely, home contacts, work contacts, medical students, and hospital nurses

PRACTICAL MEASURES

For home and work contacts protection, both of positive and of negative reactors, from the source of potential infection is likely to remain the main policy with young adults, as it is with children, though of course it may unfortunately happen that this source, whether in the home or at work, is not discovered after one or more secondary cases have already occurred Such protection of young adults like that of children, will become increasingly effective as more expeditious diagnosis and removal of sputum positive cases for residential treatment becomes practicable, as the sanatorium segregation of persistent sputum positive case becomes more widely practised, and as further advances are made in the schemes of after care so as to reduce the contact of sputum positive patients and so as to minimise their chance of relapse into this infectious state Incidentally, such measures would help to remove the growing objection of employees to the presence of an infectious fellow worker

Here I may mention the growing interest in the early recognition of infectiousness among persons with apparently minor lesions in the lung This mainly turns upon technical advances in sputum examination, such as concentration of organisms, examination of sputum contents, improved methods of culture, and examination of "morning saliva" (see Holmes 1936)

For medical students and nurses, protection from known sources of potential infection by complete avoidance of exposure is clearly unattainable The most that can be expected is the reduction of exposure to the minimum by hygienic measures, though these are perhaps more difficult to carry out in general hospitals than in special tuberculosis institutions (Joint Tuberculosis Council 1936)

If Heimbeck is right, however, we must be prepared to regard negative tuberculin reactivity in young adults exposed to contact with open tuberculosis as indicating special disadvantages—namely, a risk of clinical accompaniments to first infection and a greater risk of progressive adult type pulmonary

indications later. Special steps may therefore have to be taken for the protection of negatively reacting students and nurses, particularly if the proportion of negative at the commencement of clinical training should increase.

One suggestion is to refuse negative reactors. This course would be harder to follow with students who would already be half way through their training than it would be with nurses but even with nurses continuation of the present shortage of applicants for posts at many tuberculous institutions would create considerable difficulties. If it were decided eventually to follow such a drastic course with medical students the unfortunate man in his third year of study would be compelled not only to pass an examination in intellectual capacity to the satisfaction of the anatomists and physiologists and to pass a test of mental fitness to the satisfaction of the industrial psychologists but also to pass a tuberculin test to the satisfaction of the immunologists.

A less drastic though hardly more practicable suggestion for the protection of those tuberculin negative probationer nurses who train at a general hospital is that they should avoid the tuberculous ward, if such exists until their reactivity has changed to positive.

A third and much more promising suggestion is to vaccinate these nurses with BCG not allowing them to be brought into contact with cases of tuberculosis until their reactivity has changed to positive. The reports of recent investigations upon BCG vaccination of tuberculin negative infants (Wallgren 1931, Acreasturi and Park 1936) and nurses (Heimboek 1936) have been distinctly encouraging.

Adequate observation including periodic examination during and for some years after the period of exposure (see Jessel 1930, Lloyd and MacPherson 1936) should be used to reveal such progressive pulmonary lesions as do develop in spite of all protective measures. No methods of carrying out such periodic examination of this kind will be discussed later.

The Contacts of Ordinary Life

Measures to reduce the amount of contact with infectious cases together with improvement in housing and hygienic conditions, may be expected to increase the proportion of children who reach adult life without becoming tuberculin positive. If a negative reaction in a young adult should come to be regarded as entailing a special risk in the face of exceptional exposure the question would arise as to the risk run from exposures met with in the ordinary circumstances of life.

This has been the subject of considerable speculation. Indeed it has already been suggested (Dahl 1933) that the recent retardation in the decline of pulmonary tuberculosis mortality among young adults in this country has been partly due to an increased incidence of negative reactivity at this age with a corresponding reduction in immunity. Such an explanation is however disputed by Bradford Hill (1936) and would be untenable if as appears possible the decline in mortality in this age group once more being resumed. As a matter of fact it is known of the present degree of tuberculation of young adults of the urban working class population of England and still less of those of its rural districts. Certainly there seem to be insufficient grounds at present for any special action to protect negative reactors in particular in the population at large under ordinary circumstances of life. Nevertheless such a possibility be deemed fantastic I may refer to the procedure in recruiting for the Japanese

navy where, I am informed only positive reactors to tuberculin are accepted for service.

As to the future, we may hope that any danger of producing a large proportion of adults in the general population who would be open to the risk incurred by peoples living under primitive conditions will be offset by the fewer and smaller doses of infecting bacilli likely to be encountered by a higher standard of living of the people and possibly also by artificial active immunisation.

At the same time it is important to have records of the changing tuberculation of young adults and its relation to changing morbidity and mortality. In particular we shall do well to keep a watch for the development of classes or areas with a high incidence of adult negative reactors and a low incidence of pulmonary tuberculosis cases and other classes or areas where the opposite holds in case the movement of persons from one class or area to another may prove important epidemiologically.

Conclusions Concerning Contacts

Contact with open tuberculosis has its dangers in adult life as well as in childhood and much of the interest in the infectiousness of this disease is rightly being transferred from children to young adults. Preventive action in the future to protect adults known to be in contact with open tuberculosis is likely to aim—more than at present—at limiting the exposure, at increasing individual resistance and at maintaining close observation for the early detection of progressive lesions. Those who react negatively to tuberculin may require special protection; they may need particularly close observation should their reactivity change to positive as a result of the exposure; or they may require artificial immunisation. By a combination of preventive measures such as these with the more general social measures discussed earlier we may confidently hope that the benefit to the community from reduction in the unfavourable consequences of tuberculous infection will far outweigh any harm from loss of immunity resulting from its diminished occurrence.

(To be concluded)

THE RATIONALE OF CERTAIN METHODS USED IN PHYSICAL TREATMENT *

By SIR LEONARD HILL, M.B. Lond. F.R.S.

DIRECTOR OF RESEARCH AT THE ST. JOHN CLINIC AND INSTITUTE OF PHYSICAL MEDICINE

THE range of radiations that includes gamma rays X rays, ultra violet and infra red light and the high frequency electric waves used in broadcasting forms one great continuous spectrum of electromagnetic waves. The various regions of this differ only in wave-length the gamma rays being inconceivably short and those used in radio being many metres long. Still shorter even than gamma rays are the cosmic rays that come from the universe with great penetrating power and knock electrons off the living substance of our bodies with what effect if any we do not know.

Radium

Radium emits (a) alpha particles or rays which are helium nuclei projected at high speed and are

A lecture given at the St. John Clinic and Institute of Physical Medicine on Feb. 26th.

completely absorbed in passing through the thickness of an ordinary sheet of paper, (b) beta particles, or rays, which are electrons travelling at high speed and are stopped by 1 mm of lead, or 0.5 mm of gold or platinum, (c) gamma rays, which are photons with an average energy higher than that of X ray photons, those of the highest energy can traverse many centimetres of lead.

The X rays are generated at voltages from 10-1,000,000 kv, a range of wave lengths extending from 2 to less than 0.05 Å (Angstrom units = 10^{-7} mm). The action of the soft X rays can be compared to the beta rays of radium and that of the hard with the gamma rays.

At first it was thought that rays of different qualities were capable of producing different kinds of reactions, but it is now known that the erythema producing effect on the skin does not differ whether caused by gamma or by hard, soft, or very soft X rays. Difference in magnitude of reaction is due to the relative amount of energy absorbed per unit volume of tissue. With equal amounts absorbed in equal volumes of living substance the effects are the same regardless of the penetrating power of the rays. Thus gamma and X rays produce similar changes in the chromosomes of the nuclei of ova and similar mutations may arise—e.g., in the fruit-fly *Drosophila*. Dividing cells are those most sensitive to radiation, and in producing an effect the rate at which the rays are absorbed is very important. When a beam of high intensity is absorbed the extensive ionisation initiates destructive changes in all the cells, on the other hand, the slight damage done by a beam of low intensity can be repaired, and there may be no result. Hard rays under appropriate doses may injure the more sensitive tissues and leave others unharmed. Thus by gamma rays of low intensity the seminal epithelium alone is injured, with high intensity the entire testis degenerates.

The erythema reaction of the skin is not a good test of radiation. Minute living cells such as the ova of *Drosophila* or of the axolotl are much better, failure to hatch out being the index. The very small penetration of soft X rays and of ultra violet rays must be borne in mind. The radiation of one, or of both kinds of germ cells, before fertilisation may result in the production of monsters. Applied to developing organisms irradiation effects the most rapidly growing systems such as nervous, vascular, reproductive, and renal. Irradiation inhibits processes of regeneration in invertebrates in which processes there is taking place active division of cells. Ultra violet rays are much less effective than very low voltage X rays or cathode rays.

Repeated X ray irradiation of the skin swells the connective tissue bundles, destroys cells and thickens the cutis with shrinkage of the skin. Similar changes occur in the walls of the blood vessels, leading to occlusion, the epidermal cells swell and show abnormal mitosis. Necrosis in the superficial layer of the cutis and proliferation in the epidermis takes place and depilation may result. Ultra violet gamma, and X rays alike produce dilatation of vessels, stasis, diapedesis, and oedema. Similar intensity of the visible rays alone do not produce such destructive effects on the skin. In frost bite the rapid loss by radiation produces the same sort of damage as heat burn does.

Exposure of the body to a massive dose of X rays or radium, or the intravenous or oral administration of a large dose of thorium or radium salts or of radon, alike produce destruction of marrow and lymphoid tissue, leucopenia, degeneration of epithelium

hyperæmia of the intestines, cellular degeneration of organs, and desquamation of epithelial linings. Infra red rays produce flushing of the skin at the time of exposure, ultra violet rays after a latent period of one hour or more. For X rays the latent period is 2-5 days, and for the gamma rays of radium, weeks. The length of latency indicates the time the secondary changes take to appear in the living cell.

EFFECT OF WEAK DOSES

The giving of salts of radium by the mouth or by injection is dangerous. If taken by the mouth damage may be done to the mucous membrane of the intestines especially if the patient is constipated. When injected 80 per cent may be retained in the tissue principally in the bone marrow, disappearing very slowly. Thus deposits are formed from which radiation may be emitted for a long time. A dose of radium salts equivalent to 0.5 mg of radon element can prove fatal. Several women died licking brushes when applying a luminous radium paint to the dials of watches. The amount in their bodies varied from 0.01-0.08 mg. An American citizen died through repeated injections in order, as he thought, to rejuvenate himself. A solution containing 0.001 mg of radium and thorium per ounce of water. The activity of the emanation of radium declines to a half in 3.85 days and falls to less than 1 per cent in a month. When taken by the mouth 90 per cent is given off by the lungs in an hour, and so very little stays in the body to form an active deposit. It is soluble gas and is absorbed may reach every tissue, whereas in consequence there will be a free action of the alpha rays. Thus is not the case when radon is applied in plants or other containers, which exclude these rays.

THERAPEUTIC USES

The unit of radon is a millicurie, the amount of gas in equilibrium with 1 mg of radium element. For weak concentrations the Macho unit (M.U.) is 2,500,000 of which equal 1 millicurie. Some waters are radio active—e.g., Joachimsthal with 600 M.U. per litre and Baden Baden with 100 M.U. Artificial radio active waters are prepared generally with 8-30,000 M.U. in 1 litre as the daily dose. Continuous inhalation of radon in high concentration caused loss of weight, with leucopenia, enlargement of spleen, hæmorrhages of the lungs and glandular atrophy. It is claimed that small doses have a stimulating effect upon cell activities and are inimical to morbid states. There is no statistical evidence that spas with a high content give better curative results than spas with a low one.

In a series of cases of chronic arthritis and hypoplasia treated with a concentration of 80,000 M.U. in 15 oz of water by Howitt, Pillman Williams and Russ (1937) no benefit other than subjective was found in the clinical condition, while no injury results were noted. There is no evidence that a small quantity of radio active material in electrically heated pads is useful.

In a series of in patients treated with much larger doses—2,500,000 to 10,000,000 M.U. in 10 oz of water—no improvement was noted, except in two cases of chronic gout, more requires to be done to test the effect observed even in these two cases. Red cells fall in number when large doses are given. A sign that the treatment is risky. We must be in mind that cancer of the lung occurs to a high degree in miners who extract pitchblende, the ore from which radium is obtained. Workers in X ray radio active substances suffer from dermatitis.

particularly those who come in contact with tar or paraffin and skin cancer may result. They also suffer from anaemia and leucopenia and necrosis of the jaw bone. Sarcoma has resulted from a radon tube left in the body. In handling radium lead or tungsten alloy screens must be used and the period of work made short.

It has been shown recently that the two principal chemical systems of cell life that supply energy—respiration and glycolysis—are differentially attacked by gamma radiation applied at body temperatures. Thus tumour cells lose their power of using oxygen during a period when glycolysis remains unaffected, but if the tissues are cooled to 10° C or lower the reverse happens. Normal tissues unlike tumour cells do not use glycolysis as a source of energy except in a minor degree. Within the utilisation of carbohydrates by oxidation or by splitting processes is inhibited by gamma radiation, nitrogenous products probably proteins are broken down to supply energy to the partially damaged cells (Crabtree 1936).

Glyoxalase a ferment which was supposed to be important in the series of reactions which result in the formation of lactic acid in cells is resistant to gamma radiation. If a rat tumour is irradiated with a dose too small to visibly affect it and seven days later the tumour is irradiated and so on the effect becomes cumulative. The rate of growth and the percentage of successful inoculations falls off (Cramer 1936). Such a small dose then is harmful not stimulating to tumour cells.

Ultra Violet Light

The short ultra violet rays penetrate so slightly that their effects are limited to the epidermis and superficial capillary loops of the cutis. The absorption of products of the damaged cells causes a flush first in evidence some hour or two after exposure. The skin next day is sharply reddened; a section of it shows that leucocytes have infiltrated among the cells of the superficial layers, granules appear in the cells round the congested capillaries. In thirty hours the reaction is increased, nuclei of the superficial cells stain dimly and degenerated cells are to be seen. The pigment layer is disturbed and here and there the cutis is separated from the epidermis. The reaction now subsides but the greatest swelling of the connective tissue cells is seen on the third day. The inner layer of the epidermis pigments as it and the blood vessels return to normal. The outer layer desquamates.

One of the most important actions of the ultra violet rays is the production in the skin of vitamin D. The vitamin is produced by activation of ergosterol present in minute amounts in the sebium. This is brought about by the shortest wave lengths of the ultraviolet of about 2900 Å. These are absent in winter and screened off by smoke pollution in cities. Rickets can be prevented by suitable exposure of the skin of infants and children to the sun or are lights. Vitamin D is also obtained by eating food such as cod liver oil and particularly liver oil halibut oil being especially potent. It is formed by the action of the sun on green food of both land and sea. The milk of cows contains the vitamin when they are fed on green food, not when they are stall fed on oil cake and straw. Some animals secure this vitamin by licking except preening their fur or feathers and carnivora by eating fur or feathered animals. Vitamin A is synthesised in animals from carotin a common pigment of green plant, carrots &c. The B vitamins are plentiful in green plants but even more so in those grown in the dark. The anti-carcinogenic vitamin C

is developed not only in green plants but in citrus fruit and in germinating seeds. Certain animals such as rats can produce it in their own bodies. Vitamins are destroyed by ultra violet rays but not by that brief exposure that is required to form vitamin D.

THERAPEUTIC USES

The antirachitic effect of ultra violet light is exerted by rays at 2530–3000 Å and very weakly by those at 3130 Å. The amount of energy of the shortest wave length in sunlight—about 3000 Å—which is effective in preventing rickets is always very small. Infusoria are killed about three times as quickly with rays at 2800 Å as with those at 3000 Å while those at 3130 Å have no effect. Hemolysis is most active at 2530 Å. Erythema of the skin is produced by 2900–3000 Å and also by 2530 Å where there is a strong line in the mercury spectrum. These latter rays penetrate the epidermis less deeply than the 3000 Å rays of sunlight, and the resulting pigment is in consequence lighter in colour, thus the sun browns the skin best. Patients who do not pigment well such as red haired freckly people have to be exposed to sun treatment with care. Protection against ultra violet light is secured by thickening of the horny layer and by pigmentation of the epidermis. By giving doses that produce a mild erythema once a fortnight time is given for the erythema and desquamation to pass off and the skin again becomes sensitive. The body can be treated in four parts, thus if treatment is given twice a week, exposure of any one part is given once a fortnight. By thus plan the length of exposure can be kept short, for if the whole body is exposed each time the skin becomes less and less sensitive and to produce an effect the exposure has to be made longer and longer.

Health is stimulated by suitable doses of ultra violet rays, and immunity is said to be increased against staphylococcal infections. Overdoses cause fever irritation and depression and are dangerous to those who are fighting an active tuberculous infection. The doses for such patients must be small and carefully adjusted. The effect of absorption of products of sunburn from the skin may be compared with those of protein shock produced by injection of milk or of the patient's own blood. Ultra violet irradiation is one of the best means of producing counter irritation and blanching doses prove very useful in the treatment of scintica &c. The irradiated skin is covered with Elastoplast bandage and left untouched till healed (Hilman 1937).

Intense doses given by the water-cooled mercury lamp or the water-cooled arc are used in the Fin en Institute to heal lupus vulgaris by producing a reaction in the skin. Light treatment is also valuable for alopecia areata, eczema, psoriasis, acne, boils and carbuncles, erysipelas and septic wounds, surgical tuberculosis, and for wasting and ricketsy children. It stimulates breeding in birds, mice and monkeys, and no doubt also in man. Good pigmentation of patients is thought by A. Rollier to be a sign of well being and for wounds Oscar Bernhard the pioneer in this form of treatment uses the Alpine open air and sunlight.

Infra Red Rays

The penetrating infra red rays are of particular value in addition to the ultra violet rays—for there seems to be no antagonism in between ultra violet and heat rays. These penetrating rays relieve pain in cases of sprain &c and by softening and making supple rheumatic tissue enable curative movement.

and massage to be carried out. The long infra-red rays are absorbed by the surface of the skin and do not penetrate, they may raise the superficial temperature from 32 to 41–44° C, while the temperature 10–25 mm below the surface is not raised more than a degree above body temperature, and then only by conduction of heat. The temperature of the surface rises quickly to a maximum, and quickly drops when the irradiation ceases. On the other hand, the short infra-red and red rays by penetrating may produce a rise to 40° C 25 mm below the surface, while the surface is raised only to 38°. In this case the maximum rise and fall are reached more slowly, there is a drop of temperature from within outwards, and this is accompanied by a feeling of refreshment and relaxation. After insolation has ceased the surface of the skin quickly falls in temperature, but the deeper layers may take three quarters of an hour to fall. With the putting on of clothes after insolation the effect may last for hours.

The heating of the blood and subcutaneous tissues by the short infra red and luminous rays is one of the most important of curative effects (Sonne 1921). Pigment in the epidermis absorbs and transforms all the rays of sunlight into heat, and thus in its turn excites the nerve-endings and evokes sweating, thus overheating is prevented. A negro owing to his pigment can have a thinner skin and so lose heat more easily.

It must be kept in mind that infra-red radiation that will not go through a thin layer of water will not penetrate the epidermis. Thus only 0.5 per cent of the rays from a dark heater, 15 per cent of those from a carbon arc, and about 30 per cent of those from a tungsten arc and from the sun penetrate 1 mm of flesh. Oiling the skin by diminishing the scattering of the rays increases the penetration of the short infra red and visible rays. The value of a tungsten arc no doubt depends in part on the greater number of penetrating rays coming from this source. Sonne found during irradiation with the highest endurable intensity that the surface skin temperature rose to 43.8° C with visible and to 45.5° with the longer infra red rays. With visible rays a maximum temperature at 5 mm depth was then 47.7°, and with longer infra red rays 41.7°. The amounts in gram calories per sq cm per minute, which could be borne by the skin, was 3.11 for visible, 1.79 for shorter, and 1.33 for longer infra-red rays. The visible rays, except the red, are absorbed by the blood in the cutis, and warm this, the heat is then circulated over the body. How the red and short infra red rays penetrate beyond the cutis is seen on placing a glow lamp in the mouth and standing in front of a mirror in a dark room. A red glow comes right through the cheek, it does not do so in the case of a negro, and only to a small extent in the case of a Japanese.

I find that the long infra red rays from dark or dull red sources acting on the skin reflexly congest and narrow the airways of the nose and lungs, an effect which is set aside by cooling the skin with a fan and in some people by rays from bright sources—the antagonistic rays are in the short infra red region. The stuffiness felt in rooms heated by dark or dull red sources is due to the action of the rays on the skin, and the reflex action on the air tubes and nasal sinuses, and has, in my view, nothing to do with the chemical purity of the air. All rooms so heated should be ventilated with enough cool air to set aside the stuffiness. A greenhouse heated by the sun feels stuffy compared with the open air, because the sunlight is absorbed by the objects

within and turned into dark heat, and this is trapped by the glass, while there is no movement of the air.

For infra red treatment bright sources are those which give off the more penetrating rays, e.g., 1000 watt electric bulbs fitted with concave mirror reflectors, or the clinical gas lamp. Edison's "daylight" lamp gives relatively weak ultra red rays coming from a tubular mercury-vapour arc at low tension, together with plenty of infra red from a number of incandescent lamps, and it is an effective method of treating the whole body, as close to that of sunlight as possible.

While ultra violet rays burn superficially, they may burn deeply, such a burn must be treated with tannic acid solution, which forms a sterile coagulated protein. Heat brings blood and lymph to treated parts and softens the tissues, increases circulation and tissue metabolism has a curative effect on painful parts in cases of strain and rheumatism. One of the best methods of applying heat is by the paraffin wax bath, heated to 130°. The paraffin solidifies at skin temperature and forms a glove on the submerged part, which protects it from overheating, the vapour of sweat under the wax bath acting as an insulator. The result is a local steam bath, the part becoming flushed with blood and raised in temperature. The body temperature may be raised to 102° F by immersion of the legs above the knees. To chilblains, aching feet, and rheumatic joints the paraffin bath gives great relief.

Short Waves

Beyond the infra red is the high frequency radiation used in radio. The modern short-wave vacuum tube oscillator has allowed a study of electric waves as short as 1 metre, it is not as yet possible to generate any intensity of wave lengths less than this. Waves of 100–1 metre wave length or 3–3000 million cycles per second, and the living tissue put in the field between condenser plates, and so subjected to electrical stress, a displacement current results in which electrons in the molecules are stressed in one direction and then in another. Any free electrons also tend to pass from molecule to molecule forming a conduction current, and the molecules themselves, if bi-polar, tend to rotate in response to the changing potential of the field. The result is heating of the tissues. Artificial fever can be produced by putting the whole body, with exception of the head in the field of the high frequency current. The temperature may be raised to 105° F 60–80 mins. By so heating the body for some bacterial infection is destroyed. General paralysis of the insane has been treated successfully by this method in place of artificial production of malaria. Local heating can be produced by the local application of the electrodes—e.g., on either side of the face the temperature in the mouth thus being raised to 102–103° F an effect that cannot be produced by hot bottles placed on either cheek, or by ordinary diathermy. A local heating of the rectum can similarly be obtained. Small tumours grafted in the flanks of rats can be destroyed by the heating effect of the field, with some damage also to the skin. There is no evidence of any specific effect apart from heat, for heart, cilia, and muscle nerve preparations of the frog put in the field and kept cold suffer no change. If they are not kept cold they become affected by rising temperature, brought about by the high frequency field just as when heated by any other means. By intra pelvic diathermy heat treatment may be given with great advantage to certain cases.

of inflamed cervix or prostate especially in gonorrhoeal infection and backache and rheumatic troubles may also be relieved (Robinson 1920). In such cases the heat brings more blood and lymph to the treated part, and increases metabolic change and so produces a curative effect.

Natural Sources

Exposure to cold in open air treatment is effective in stimulating body metabolism and appetite. Still more so sea bathing for the resting metabolism may be increased by 50-100 per cent. in children exposed to the open air and 10 times while bathing in the sea. Cold stimulates the nervous system and drives the blood inwards while heat flushes the skin. Such to and fro changes promote health. It is of interest to note that sterility has been produced experimentally by keeping the testicles warm all the time. The breathing of cool air promotes evaporation from the respiratory membrane and stimulates secretion and the flow of blood, thus cleansing the membrane. The secretion of the membrane is a defence against infection. Cold air widens the breathing tube stimulates body activity and causes deep breathing which occasions a natural massage of the abdominal organs.

ADDISON'S DISEASE DUE TO SUPRARENAL ATROPHY WITH PREVIOUS THYROTOXICOSIS AND DEATH FROM HYPOGLYCAEMIA

By IAN A. ANDERSON, M.B. B.Sc. Aberd.

ASSISTANT IN MEDICINE, UNIVERSITY OF ABERDEEN AND

ALEXANDER LYALL, M.D. Aberd. M.R.C.P. Lond.

LECTURER IN CLINICAL CHEMISTRY IN THE UNIVERSITY

This patient, a single woman was first seen on August 28th 1920 when she was 30 years of age. At that time her history was that weakness, loss of weight, prominence of the eyes and swelling of the neck had developed during the last three years. She was a well developed woman (height 5 ft 4 in; weight 9 at 8 lb) presenting the characteristic signs of thyrotoxicosis. Her basal metabolic rate (B.M.R.) was +42 per cent. having confirmed this diagnosis by the following results:—

On Nov. 6th of the same year having had three exposures to X rays she weighed 10 at 3 lb and the tremors and vasomotor disturbances had disappeared but exophthalmos remained. The B.M.R. was now +18 per cent. On April 8th 1930 after two further exposures to X rays her improvement was maintained and the thyroid gland was no longer palpable. Her weight was now 10 at 4 lb and the B.M.R. +20 per cent.

She was not seen again until Jan 10th 1930. In the interval she had resumed her work as a typist and had remained in good health until 1935.

During the summer of that year she had become very sunburnt; the pigmentation did not fade subsequently but rather increased and in September she had a severe attack of colicky epigastric pain accompanied by vomiting and pain in the back and swelling of the eyelids. She returned to work however and between September 1935 and

January 1936 she felt quite well although she was rather easily tired and the pigmentation of the skin persisted.

In January 1936 she began to have attacks of pain and a sinking feeling in the stomach accompanied by nausea. These symptoms lasting for a few days at a time. She also developed an aversion to salt or food the least bit salty and was more sensitive to cold weather than before. When she was seen on Jan 10th the pigmentation of the skin was striking. It was brown in colour and present on the face lips backs of the hands areolae and axillae. She now weighed only 8 st but otherwise physical examination revealed no abnormality. The pulse rate was 68 the blood pressure 120/90 mm Hg and the B.M.R. -21 per cent. The blood chemical findings on this occasion were: blood urea 37 mg per 100 c.c.m. fasting blood-sugar 62 mg and plasma chloride (expressed as sodium chloride) 511 mg. The urinary chlorides in a sample taken at the same time as the blood sample were 480 mg.

A diagnosis of subthyroidism was made and also a tentative diagnosis of Addison's disease in view of the pigmentation, loss of weight, gastro-intestinal symptoms and slightly subnormal plasma chloride level. The patient was put on thyrodoxin siccum (B.P.) one-quarter of a grain daily the small dose being given in view of the sensitivity of patients with Addison's disease to thyroid extract. Her symptoms after a short remission became severe again and she was admitted to hospital on Feb 20th 1936 thyroid administration being stopped.

FIRST STAY IN HOSPITAL

The pigmentation had now become deeper, being present over the abdomen and in the skin creases of the palmar surface of the hands. Her weight was only 7 at 2 lb her pulse-rate was 104 and her blood pressure 88/61 mm Hg. Blood urea 40 mg per 100 c.c.m. fasting blood sugar 65 mg and plasma chlorides 526 mg.

As her symptoms were not considered of extreme urgency she was at first kept under observation with no special treatment the blood chemistry being examined daily. There was a slight improvement in subjective symptoms during the first five days after admission but the plasma chloride level declined slowly as is shown in the Figure.

On March 1st menstruation began, and the flow lasted for four days, no blood samples being taken during this time. On the 6th two days after the period had ceased the patient complained of nausea and began to vomit after meals. The plasma chlorides showed a further fall.

On March 9th her temperature rose to 101 F and she developed dull abdominal pain accompanied by tenderness but no rigidity. As the plasma chlorides had fallen to 470 mg per 100 c.c.m. the blood urea had risen to 67 mg and the blood pressure had fallen to 70/50 mm Hg treatment with suprarenal cortical extract was begun 5 c.c.m. of Supracort (Paines and Hyne) being injected intravenously twice daily. No intravenous saline were given at this time but an attempt was made to commence sodium chloride therapy by mouth. However the patient vomited salt given in formalised gelatin capsules and this treatment was abandoned temporarily after one day.

In spite of the hormone injections the plasma chloride continued to fall for three days being 438 mg per 100 c.c.m. on March 12th. The subjective symptoms improved however and the blood pressure had risen to 94/66 mm Hg by the 12th; the fall in plasma-chloride concentration for three days

A note on *Irelanda*—Chloride estimations were made on plasma throughout by the method of Van Slyke and Mendry (1923). Blood samples were collected with a 21 gauge needle under oil in small sample tubes which were practical & filled with blood; separation of plasma and analysis were performed at once. Blood urea and blood-sugar estimation was carried out by the method of Jellison.

after hormone therapy was probably due to dilution of the blood, following hemoconcentration during the crisis, although no confirmatory hæmatocrit estimations were made. That such dilution occurs after hormone therapy in suprarenal insufficiency is recognised from the work of Swingle and Piffner (1933), Harrop (1933, 1936), and Loeb (1933).

On March 13th the plasma chlorides had increased to 502 mg per 100 c cm and next day salt therapy was begun again, the patient taking 2 grammes of sodium chloride in a cup of water thrice daily. This method of giving salt caused much less nausea than the formolised gelatin capsules, a fact noted also by Kepler (1935) in recording the treatment of Addison's disease at the Mayo Clinic. Hormone injections were discontinued on March 14th, and the patient was now receiving 6 g of sodium chloride daily as the only special treatment. She was feeling very much better now, and was eating food with relish. As her plasma chlorides only just reached a normal level and began to decline again, the dose of sodium chloride was increased to 8 g daily, but this did not prove sufficient to raise the plasma chlorides to normal, and the dose was further increased to 10 g daily. The plasma chlorides quickly rose to normal on this second increase in the dose of salt and continued there during the rest of her stay in hospital, and the patient noted a definite improvement in her symptoms. Her strength and appetite both improved, and she was now able to walk round the ward. The cutaneous pigmentation decreased in intensity, and her weight, which had fallen 2 lb since admission, began to rise.

To test the observation made by Blankenhorn and Hayman (1935) that other sodium salts could be substituted for sodium chloride without detriment in the treatment of Addison's disease, on March 25th the patient was taken off sodium chloride alone, and given 4 g each of sodium acetate, sodium bicarbonate, and sodium chloride thrice daily, this being equivalent to 10 g of sodium chloride in sodium content. This treatment was continued for five days, during which the plasma chlorides fell slightly, but kept well within normal limits (see Figure) while the subjective condition remained unchanged, thus providing a confirmation of Blankenhorn and Hayman's work.

During her stay in hospital, the patient showed a strong tendency towards fasting hypoglycaemia. The fasting blood-sugar readings were —

Jan 19th	62 mg per 100 c cm
Feb 27th	65 " " "
" 29th	77 " " "
March 9th	113 " " "
" 10th	67 " " "

Radiography of the abdomen revealed no evidence of calcification of the adrenals. The lungs were radiologically normal, and there were no signs of tuberculous elsewhere in the body. The B M R on March 21st was -27 per cent. The patient was discharged on April 1st, having been given instructions to take 10 g of salt daily.

SECOND STAY IN HOSPITAL

About a fortnight after leaving hospital on April 1st the patient began to suffer from stiffness and later pain, in her knees, worst at night and in the morning. Otherwise her health was satisfactory and she took her salt regularly. During August and September she received thyroideum siccum (B P) gr 1 twice daily. She had no vomiting or abdominal pain, but her appetite deteriorated. On readmission on Oct 5th the pigmentation was somewhat lighter than before, the pulse rate was 84 and the blood pressure

105/78. Both knees were held in semiflexion, and movements were slow owing to spasm of the quadriceps and hamstring muscles. Coarse joint crepitus was felt on movement, which was painful. A radiogram showed typical early osteoarthritic changes in both knees, but it was agreed that the joint changes could not be held responsible for the extreme degree of spasm present. The patient had always been a difficult nursing case, but her irritability and intractability had now much increased.

On the morning of Oct 10th, five days after admission, she became drowsy and confused. The spasm of the leg muscles had increased, and the feet were held rigid in an inverted position with the toes hyperextended. This spasm spread to the arm muscles, masseters, sternomastoid, and respiratory muscles, it was tetanic, with occasional superimposed twitches. The patient was semiconscious, responding only to painful stimuli, and her systolic blood pressure was 65 mm Hg. No cortical extract was available, and 10 c cm of 10 per cent calcium levulinate solution had no effect on the spasm, which increased in intensity. The blood chemical findings, received about two hours after the first appearance of the spasm, were: blood urea 34 mg per 100 c cm, plasma chlorides 536 mg, blood-sugar, no reducing substance present. As the peripheral veins were so collapsed that intravenous injection was impossible, 100 c cm of 50 per cent glucose solution was administered by nasal catheter, and 8 minims of 1/1000 adrenaline solution injected intramuscularly. The patient, who was deeply comatose by this time, showed a dramatic response to this treatment. Within 25 minutes of receiving the glucose she regained consciousness and complained of great pain in her knees. Instructions were given to continue treatment with glucose and fluids by mouth. In the early afternoon she was able to talk to her relatives but later in the day she became drowsy and relapsed into coma. Adrenaline was injected without effect and she died that night.

POST-MORTEM EXAMINATION

There was atrophy of both suprarenal glands, with hyperplasia of the lymphoid tissue of the bowel, and to a less extent of the lymph nodes throughout the body.

Both suprarenal glands were reduced to small flattened pieces of tissue, the left gland measured only 40 by 22 by 17 mm. The capsule and superficial arteries were clearly seen. Microscopically, the glandular tissue had disappeared, and only a few scattered cortical cells remained. Some of these showed proliferative activity and contained two nuclei, while others were necrotic and undergoing degeneration. The reticulum of the medulla with its blood sinuses could still be made out, but only one or two medullary cells were seen. The place of the glandular tissue of cortex and medulla was taken by a small amount of fibrous tissue, which was heavily infiltrated with lymphocytes, amongst which there were a few macrophages and plasma cells.

The thyroid gland was of moderate size. Microscopically, it showed extensive degenerative changes, with accumulation of lymphoid tissue, an extensive fibrosis of the stroma and thickening of the walls of the blood vessels. Residual nodules of thyroid tissue remained, these being composed of small acini lined by a single row of cubical epithelial cells, many of which contained pyknotic nuclei and were in the process of degeneration. Most of the acini contained a small amount of deeply staining colloid. The liver showed fibrosis of many of the portal spaces, which contained giant cells, and were surrounded by a ring of lymphocytes. Some of the liver cells towards the central vein showed degeneration, and had pyknotic nuclei.

The parathyroid glands appeared normal.

Permission to examine the head was refused, so that the pituitary gland could not be examined.

Discussion

Cases of Addison's disease associated with thyrotoxicosis have only rarely been reported (Etienne 1910 Etienne and Richards 1926 and Chausfard and Girot 1926 and Brenner 1928-29). As in the present instance the symptoms of Addison's disease have usually followed those of thyrotoxicosis.

The thyroid gland often shows pathological changes in Addison's disease although such changes as are described show no uniformity. Crooke and Russell (1935) described evidence of increased thyroid

activity—tubular often branched tubular and rounded acini either empty or containing a little coagulum with lymphocytic infiltration. Brenner (1928-29) reported fibrosis and lymphocytic infiltration of the thyroid the parenchyma of which showed signs either of increased or of diminished activity—some times as much diminished as in myxoedema. He thought it probable that the changes in the thyroid were due to the same cause as the suprarenal lesion and not secondary to loss of suprarenal function.

As would be expected from the pathological changes in the thyroid the B.M.R. is often altered in Addison's disease. It is usually depressed—about -7 to -8 per cent according to Greene (1931). The case here recorded showed a depression (-27 per cent) as low as in a fully developed case of myxoedema, and the question arises whether the previous treatment of the thyroid with X rays had made it more susceptible to the degenerative changes which so often accompany Addison's disease.

Conversely it may be asked whether the degeneration of the suprarenal glands was in any way associated with the previous Graves' disease or with its treatment with X rays. There is some experimental evidence that the adrenal cortex inhibits the activity of the thyroid. Thus Marano and Baumann (1921) found that incomplete destruction of the suprarenal cortex in rabbits with intact thyroids—but not in

those with thyroids removed—cause a rise in body temperature and suggested that suprarenal insufficiency might be the cause of thyrotoxicosis. Koelsch (1934) showed that the suprarenal cortical hormones inhibited the stimulating effect of thyroxine on protein metabolism. On the other hand, evidence is lacking that destructive lesions of the thyroid affect the suprarenal cortex if they did, suprarenal insufficiency would have been more often observed in the large numbers of patients who have undergone thyroidectomy or radium or X ray treatment of the thyroid.

Apart from the association of thyroid disease with Addison's disease the clinical history of the patient during her first admission to hospital presented two other interesting features:—

(1) She had a strong distaste for salt or salty food and it was very difficult to make her take salt until she realised that it made her feel better. This contrasts with the reports of other observers. Thus Snell (1934) and Haussen (1936) both reported cases with a craving for salt.

(2) The crisis immediately followed a menstrual period. This relationship between menstruation and increased severity of symptoms in Addison's disease has been commented on by Weller (1936) one of whose patients had monthly attacks of vomiting at the time of expected but absent menstrual

periods. The increase in suprarenal insufficiency is presumably due to the added stress of the menstrual period which increases the need of the body for cortical hormone.

OBSERVATIONS ON CHLORIDE EXCRETION IN ADDISON'S DISEASE

In normal persons the excretion of chloride by the kidneys is so controlled by the requirements of the body that the concentration and the total amount of chloride in the plasma and tissues is maintained at a constant level. If the plasma concentration falls below normal the excretion of chloride in the urine falls to a negligible amount. This is well shown in a series of experiments by Altman (1929) in which the plasma-chloride concentrations of normal persons were reduced by placing them on a salt free diet and

Chart showing chemical findings in relation to treatment (first admission)

encouraging chloride loss by water drinking and sweating. When the plasma chloride concentration fell below 555 mg of NaCl per 100 c cm the urinary excretion of chloride reached the approximately constant and negligible minimum of 5 mg NaCl per hour.

It is only rarely that the kidney excretes chloride in anything but minimal amounts at levels of chloride in the plasma below 530 mg per 100 c cm. Such an alteration in what is usually called the "chloride threshold" occurs in Addison's disease, and occasionally in diabetes mellitus and chronic nephritis. In the latter diseases urinary chloride excretion at subnormal plasma chloride levels, when it occurs, is probably due to pathological changes in the renal parenchyma. In Addison's disease this chloride loss is due to lack of the hormone of the suprarenal cortex, one of the functions of this hormone being the control of sodium metabolism and the distribution of body water (Harrop and Weinstein 1933, Harrop 1936, Loeb, Atchley, Benedict, and Leland 1933). In the absence of the hormone, there is a drainage of sodium, accompanied by chloride, from the body.

To demonstrate this loss of the power of the kidney to conserve chlorides in Addison's disease, observations were made on our patient during her first admission to hospital. On each occasion that a blood sample was taken for estimation of plasma chloride, she emptied her bladder fifteen minutes beforehand, and then passed urine just after the blood sample had been taken. The second specimen of urine was assumed to represent the urinary chloride excretion at the level of the plasma chloride found in the blood sample. As can be seen from the accompanying Table, urinary excretion of chloride continued for

While such a loss of chloride conserving power is not specific for Addison's disease, being sometimes found also in nephritis and diabetes mellitus, it may be of some value in the differential diagnosis of Addison's disease, especially in cases without pigmentation. In the absence of evidence of diabetes or renal disease, the finding of a chloride concentration in the urine of over, say, 200 mg per 100 c cm, when the plasma chloride concentration is below the minimal normal level of about 530 mg per 100 c cm, would strongly suggest the presence of Addison's disease.

SPONTANEOUS HYPOGLYCAEMIA IN ADDISON'S DISEASE

The striking terminal phenomena after the patient's second admission to hospital were the coma and generalised muscular spasm, associated with severe hypoglycaemia.

Similar symptoms in the course of Addison's disease have previously been reported. Thus, in the first of the cases reported by Weller (1936) there was drowsiness and spastic contraction of the right arm, which Weller associated with the hypoglycaemia noted in the patient during a previous admission to hospital. In the sixth of the cases reported by Hanssen (1936) there was an episode almost identical with the symptoms shown by our patient.

The patient, a woman of 47, with Addison's disease of tuberculous origin, became confused and maniacal, and developed paralysis of the right arm and a bilateral extensor plantar response. Blood sugar determinations made during the course of this episode showed values as low as 40 mg per 100 c cm, and the symptoms cleared up after the rectal administration of glucose. Hanssen suggested that the sudden death which sometimes occurs in Addison's disease, with no haemoconcentration or other blood chemical findings characteristic of crisis, might be due to spontaneous hypoglycaemia.

Investigation of suprarenalectomised animals has shown that, in certain species at least, removal of the suprarenal glands causes a profound disturbance in carbohydrate metabolism. Britton and Silvette (1932) have demonstrated that in the guinea pig and cat suprarenal insufficiency is accompanied by reduction in liver glycogen and blood sugar, and that animals dying of suprarenal insufficiency show convulsive seizures similar to those observed in insulin hypoglycaemia. These authors consider that the convulsions are related to the hypoglycaemia, which, in their opinion, is the immediate cause of death. Similarly, Harrop and others (1935) have shown that in suprarenalectomised dogs, maintained either with cortical hormone or with salt, fasting produces weakness and coma, associated with extreme hypoglycaemia, but with no fall in plasma sodium or chlorides and no rise in blood non protein nitrogen, and that glucose injection rapidly relieves the symptoms.

Recent work (Britton and Silvette 1934, Buell, Anderson, and Strauss 1936) has shown that animals suffering from suprarenal insufficiency have lost the ability to form liver glycogen from injected glucose or sodium lactate. The weight of evidence therefore suggests that the suprarenalectomised animal develops hypoglycaemia because it cannot form liver glycogen as a store to maintain its blood sugar level. Since anorexia is common in Addison's disease, the failure to form liver glycogen from endogenous sources may well be the cause of the hypoglycaemia so often noted in this disease, and may explain the occurrence of coma in the absence of any changes in blood volume or plasma electrolytes.

In our patient, the plasma chlorides and blood urea were both within normal limits at the time

several days after the plasma chloride concentration had fallen well below the usually accepted minimal normal level of about 530 mg per 100 c cm.

As a contrast to this case similar observations were made on a series of cases with high intestinal obstruction vomiting and hypochloraemia. In both cases presented in the Table the urinary chloride concentration during the period of hypochloraemia was very low below 100 mg per 100 c cm. As soon as the plasma chloride concentration rose to above 530–540 mg chloride appeared in the urine in normal amounts confirming the observations of Aitken (1929) mentioned previously.

of the terminal symptoms and thus two of the characteristic blood chemical findings of an Addisonian crisis were lacking. On the other hand, there was extreme hypoglycaemia and we hold that the coma and muscular spasm can be directly related to the hypoglycaemia. Although serum calcium and plasma alkaline reserve determinations were not carried out the muscular spasm was obviously not of the nature of tetany since it was unrelieved by calcium injection and the dramatic recovery of consciousness and the disappearance of the spasm after the administration of glucose and adrenalin made the diagnosis of hypoglycaemia certain.

It is less certain whether the fatal termination in spite of glucose treatment can be attributed to hypoglycaemia but Rabinovitch and Barden (1932) have reported a case which seems to make this opinion at least tenable. Their patient a youth of 17 suffered from spontaneous hypoglycaemia due to replacement of the suprarenal medulla by lymphoid tissue. He developed coma and spastic contraction of the right arm with a blood-sugar concentration of 25 mg per 100 c.c.m. Recovery of consciousness followed continuous intravenous glucose infusion but the blood-sugar remained low despite this treatment, and he finally relapsed into coma and died. In this case the suprarenal cortex was comparatively undamaged so that Addisonian crisis can be excluded as the cause of death.

Summary

A case of Addison's disease due to suprarenal atrophy and preceded by thyrotoxicosis is described. Death occurred in hypoglycaemia.

It is suggested that simultaneous determinations of the plasma chloride and urinary chloride concentrations are of value in the diagnosis of early cases of Addison's disease.

We are indebted to Prof. Stanley Davidson for permission to publish this case and to Dr. William Davidson for the post-mortem report.

TORREY HOSPITAL.—Eight acres of land on the western side of this hospital have been purchased. Accommodation is being provided for another 22 patients and a public appeal for the funds has brought in enough to liquidate the amount due to the contractor. About £6000 has been obtained from the contributory association. The out-patient attendance reached 36,718 over 10,000 more than in the previous year.

TREATMENT OF URINARY INFECTION THE IMPORTANCE OF DIETARY CONTROL

By HERBERT I. COOMBS B.Sc. Oxon. Ph.D. Camb.
M.D. Harvard

CHARLES H. CATLIN M.B. Birm. D.A.

AND

DOROTHY READER M.B. Birm.

(From the Biochemical Laboratory, The Queen's Hospital, Birmingham)

MANY of the methods of treating urinary infection have necessitated some control over the reaction of the urine. A satisfactory degree of alkalinity can usually be produced by the administration of sodium bicarbonate or potassium citrate provided adequate dosage is employed but acidification has always been much more difficult to achieve. Control of the acidity of the urine became important with the introduction of the use of hexamine but strict control has only been attempted since the adoption of the ketogenic diet and mandelic acid treatment.

When hexamine was first used the somewhat obvious agent acid sodium phosphate was generally employed to acidify the urine and this drug has had a wide vogue ever since. Some doubts however were cast on its efficacy as early as 1913 (Henderson and Palmer) and since the work of Haldane (1921) the administration of ammonium salts such as the chloride nitrate or more recently phosphate has gained favour.

Diet apart from drugs also markedly influences the reaction of the urine and can if suitably arranged nullify or reinforce the action of drugs.

KETOGENIC DIET

In 1931 Clark investigated the effects of giving patients a diet containing a large quantity of fat but the minimum of carbohydrate. This lack of carbohydrate causes incomplete combustion of the fat, with the result that certain acids of which β -hydroxybutyric acid is the most important appear in the urine. These acids fulfil two purposes: they make the urine acid and they act as bactericidal agents.

Very satisfactory results were obtained by this method but the diet is extremely unpleasant and many patients have difficulty in tolerating it. In order to eliminate the troublesome dietetic regime attempts were made to administer the β -hydroxybutyric acid by mouth but it was found as expected that it is completely oxidised in the body and does not appear in the urine. Rosenheim (1935) however discovered in mandelic acid an excellent substitute which can be given by mouth and yet escape oxidation and appear in the urine in sufficient quantity to be effective. With this drug the need for a low pH still exists and it is probable that many failures of mandelic acid treatment are due to the inadequate acidification of the urine. Some investigators have thought that a modified ketogenic diet might serve to lower the pH of the urine sufficiently for the mandelic acid to be effective. Actually unless this type of diet is imposed with the utmost rigour and care it has no effect whatever on the reaction of the urine (even comparatively slight variations from the strict regime rendering it entirely valueless).

OTHER DIETARY MEASURES

There are fortunately other dietetic methods of changing the reaction of the urine which are easily tolerated.

For the past thirty years considerable knowledge of the mineral content of foods has been available but seems to have been given little practical application. Nearly all foods contain acid- or alkali-producing elements in varying proportions, so that after oxidation there remains an ash having a preponderance of acidity or alkalinity. Sherman and Gettler (1912) investigated the composition of many foods and, by estimating the sodium, potassium, calcium, magnesium, sulphur, phosphorus, and chlorine content, were able to calculate the excess of acidic or alkaline radicals present (see Table).

Table showing Acid base Balance of Foods

Equivalent acid or alkali per 100 grammes edible foodstuff

ALKALI PRODUCING FOODS

Foodstuff	Normal alkali (c.cm.)	Foodstuff	Normal alkali (c.cm.)
Almonds	11.3	Horse radish	5.5
Apples	3.4	Jelly	3.6
Apricots	7.2	Leeks	7.1
Asparagus	1.3	Lemons	4.8
Bananas	8.4	Lemon juice	4.6
Beans dried	11.7	Lettuce	7.7
" fresh string	5.6	Limes	11.5
Beets	11.1	Maple syrup	12.5
Blackberries	3.5	Milk cow's whole	1.8
Cabbage	4.3	" skimmed	1.7
Cabbage greens	2.8	" condensed	4.3
Cantaloupe	15.2	" goat's	5.9
Carrots	10.9	" human	0.8
Cauliflower	5.3	Molasses	31.0
Celery	8.7	Mushrooms	2.4
Cherries red	5.6	Musk melon	7.5
Chestnuts	12.6	Olives	48.0
Chocolate	7.0	Oranges	0.1
Cider	3.5	Orange juice	5.7
Citron	9.9	Parsnips	11.4
Cocoa	5.7	Peaches fresh	5.8
Coconut dried	2.3	Pears	3.1
" fresh	2.2	Peas dried	3.7
Cream	1.4	Pineapple	6.9
Cucumber	1.3	Potatoes	8.2
Currants dried	10.6	Pumpkin	1.5
" fresh	4.0	Radishes	4.7
Currant juice	5.3	Raisins	22.8
Dandelion	18.8	Rhubarb	0.2
Dates	12.6	Splanch	22.9
Fadive	11.4	Strawberries	6.7
Figs, dried	28.4	Tomatoes	5.3
" fresh	9.4	Turnips	7.5
Grape fruit	4.1	Turnip tops	18.9
Grape juice	2.9	Watercress	11.3
Grapes	3.8	Water melon	2.2
Hazel nuts	5.4	Whey	2.4
Honey	0.5	Wine average	2.1

Jams have approximately two thirds the values of the corresponding fruits

ACID PRODUCING FOODS

Cranberries plums prunes

NEUTRAL FOODS

Butter, cornflour, fresh peas lard onions, sugar, tapioca, vegetable oils

The above Table is compiled from several sources but is calculated almost entirely from the sodium, potassium,

magnesium, calcium, sulphur, phosphorus, and chlorine figures given recently by Sherman (1932)

Their results were expressed in terms of the number of cubic centimetres of normal acid or alkali available from 100 grammes of each food. The residue resulting from oxidation within the body is excreted by the kidneys and intestine, and thus tends to influence the reaction of the urine. With most foods the effect on the urine is exactly as the ash analyses would lead us to expect, but a few fruits—i.e., plums, prunes, and cranberries—act as acid producers in the body in spite of yielding an alkaline ash. This apparent anomaly is explained by the fact that these fruits contain appreciable quantities of benzoic acid which escapes oxidation in the body and is excreted in the urine in conjugation with glycine as hippuric acid.

METHODS OF INVESTIGATION

A number of healthy men and women were placed on acidogenic and alkalogenic diets similar to those shown herewith.

ACIDOGENIC DIET

Breakfast—Porridge or cereal with sugar and cream. Bacon and egg, bacon and kidney, or fish. Bread and butter.

Lunch—Meat, chicken, or fish, or omelette (cheese or savoury). Stewed prunes and cream. Bread and butter. Cheese and biscuits.

Tea—Minimum of tea with sugar and cream. Bread or toast with butter, or egg or sardine sandwiches.

Supper—Meat or fish or cheese. Bread and butter. Walnuts. Minimum of coffee with cream and sugar.

ALKALOGENIC DIET

Breakfast—Half grape fruit or orange with sugar. Mushrooms and tomatoes on minimum of toast. Mixed fruit—dates, apples, or bananas. Tea with milk and sugar.

Midmorning—Glass of milk with apple or banana.

Lunch—Vegetable soup (celery, tomato, parsnips, turnips, onions, &c., but no meat stock, barley, or lentils). Green salad (tomato, cress, lettuce, cucumber, celery). Date and almond salad, baked apple, stewed fruit and junket, or raw fruit.

Tea—Tea with milk and sugar. Green salad raw vegetable salad or fruit salad. Minimum of bread and butter.

Supper—Vegetables en casserole (onions, carrots, turnips, tomatoes, &c.) Potatoes. Stewed fruit and cornflour mould, raw fruit or almonds and raisins. Coffee with milk and sugar. Golden syrup may be taken with any meal.

The urine was collected at two hourly intervals throughout the day and the pH of each specimen determined colorimetrically with as little delay as possible. The essential features of the acidogenic diet are the inclusion of meats, fish, bread, cereals, cheese, butter, and eggs, with plums, prunes, and cranberries as dessert. All of these foods have a comparatively low water content so that it was easy to arrange that subjects on this diet had a low urinary output. On the other hand the main articles of food in the alkalogenic diet—namely, potatoes, milk, fruit, and vegetables—all contain a large quantity of water and this makes it somewhat difficult to ensure a very low urinary output. Fortunately, as explained below, this is not of great consequence.

RESULTS

The results of an experiment on a healthy male are given herewith (Fig. 1) and similar results were obtained with several other individuals.

It will be seen that a normal person can render his urine relatively alkaline or markedly acid merely

by suitable selection of his food. It is clear that the attainment of an acid urine by the administration of drugs would be far more difficult in a person on a vegetarian diet than in one on a mixed diet. In order to test this point further the urine of individuals on an alkalogenic diet was collected and sufficient normal hydrochloric acid added to each sample to bring the pH to 5.3. On the average the total volume required to be added to the 24 hours output of urine was about 75 c.c. which is equivalent to the daily dose of ammonium chloride usually prescribed—namely 4 grammes. It can thus be seen that in a patient eating a vegetarian diet this dose will only be effective in producing a highly acid urine under ideal conditions. As shown in Fig. 1 however it is possible to maintain the reaction of the urine below 5.3 by diet alone. If drugs are used the diet will reinforce their effect.

Experiments were carried out to ascertain the effect of the ingestion of various amounts of water on the reaction of the urine. It was found that dilution of urine with distilled water *in vitro* has very little effect on the pH. Urine of pH 5 even when diluted tenfold which is far outside usual physiological limits generally changes to pH 5.2. Moreover in the experiment shown in Fig. 1 the subject restricted his fluid intake during all days on the acidogenic diet with the exception of Nov. 3rd. On this day large quantities of fluid were taken but it will be seen that the effect on the reaction of the urine is not very great. Even this small decrease of acidity is of importance however and patients on an acidogenic diet should restrict their fluid intake as much as possible not only to achieve the maximum acidity but more important to keep the urinary concentration of mandelic acid, or other antiseptic which may be prescribed as high as possible. When alkaline drugs are being administered the small

PRACTICAL APPLICATION

The above facts were demonstrated on several patients. Allowing them their own selection of diet and placing no restriction on acid fruits

such as oranges and lemons it was found that the average pH of the urine was 5.5 or even 6 under the usual dosage of mandelic acid preparations. On correcting the diet the pH could be maintained below 5.3. These facts are illustrated by the following case.

An otherwise healthy male aged 22 years complained of severe pain in the right loin. During the next fortnight he suffered intermittently from this pain and had a widely swinging temperature. He then passed a small stone and noticed that his urine was cloudy. Alkali was administered for the next month but without effect. He was referred to hospital and placed on the usual dosage of a well known preparation of mandelic acid containing phosphates as an acidifying agent. During the next ten days it was noticed that the average reaction of the urine was about 5.8. On the tenth day of his stay in hospital the urine was collected at three hourly intervals throughout the day and night. On the eleventh and subsequent days the patient was given an acidogenic diet. No other alteration was made in the treatment and the satisfactory change of the reaction of the urine is shown in Fig. 2.

FIG. 2.—The effect of an acidogenic diet on the urine of a patient receiving mandelic acid. Before the diet the average pH was 5.8. Each day began at noon just before lunch. Up to and including the tenth day in hospital the patient selected his own diet. On the following days an acidogenic diet was given.

FIG. 1.—Effect of acidogenic and alkalogenic diets on the urine of a healthy male. Each day began at 8 A.M. Just before breakfast. Several days are omitted from the complete experiment for reasons of space. A line is drawn at pH 5.3 and reactions above and below this line are shaded. On all days when an acidogenic diet was taken fluid was restricted except on Nov. 3rd when large quantities of fluids were taken. The effect of slightly raising the pH. It will be noticed that about 40 hours of an acidogenic diet were required on Nov. 13th and 14th to "wash out" the effect of the previous ten days' alkaline diet. After this the pH of the urine did not rise above 5.3 except for 4 hours on Nov. 15th when it rose to 6.3.

effect of dilution on the reaction of the urine can be disregarded as clinical experience seems to show that a marked diuresis is essential in the treatment of cases in which these drugs are used.

It will be noticed that there is very little evidence of acid or alkaline tides in the above results, but on some occasions unexplained variations of pH occurred at approximately similar times of the day. These variations were probably connected with the habits of the individual. There is no doubt that the usual acid or alkaline tides must be dependent to a great extent on the activity of the individual the times at which meals are taken and especially on the nature and quantity of the food ingested.

The above results show that the reaction of the urine can be much influenced by the diet both in normal persons and in patients suffering from urinary tract infections. It would seem expedient therefore to adjust the diet in all cases where the maintenance of an acid or alkaline urine is of importance. In many cases this control of the diet need not be rigid slight modifications which are hardly noticed by the patient often being sufficient. It has been found that a strict alkalogenic diet can be taken for long periods without inconvenience. A strict acidogenic diet however may sometimes result in slight gastric discomfort but this together with the slight dyspnoea which often occurs may be a manifestation of the acidosis and therefore inevitable.

SUMMARY

- (1) Urine can be rendered and maintained relatively alkaline or highly acid by administration of the compound of alkali or of acid producing foods.
- (2) Modification of diet for this purpose are of an useful in the treatment of urinary tract infection.

(3) A table of acid and alkali producing foods is presented

JAUNDICE COMPLICATING PNEUMONIA

WITH SPECIAL REFERENCE TO JAUNDICE WITH
CHOLEMIA AND ITS TREATMENT

By C ALLAN BIRCH, M D Liverp.,
M R C P Lond., D C H., D P H.

SENIOR PHYSICIAN, NORTH MIDDLESEX COUNTY HOSPITAL

JAUNDICE is not a common complication of pneumonia. Amongst 800 cases of lobar pneumonia and broncho pneumonia in the last three years at the North Middlesex County Hospital only 2 were recorded in which severe jaundice was thought to be a direct complication of pneumonia. One is described in this paper and in the other the patient died shortly after admission. A slight icteric tinge is seen more often, and Elton (1931) has shown that latent jaundice as manifested by the van den Bergh reaction is almost constant in pneumonia.

Many workers have investigated the cause of jaundice complicating pneumonia. Preti (1932) concludes that in pneumonia bilirubin may be formed in the lung itself and by entering the circulation may give rise to clinical jaundice. Chierici's (1932) findings, too, suggest that during the stage of red hepatisation bilirubin is formed outside the liver in the pneumonic focus. Mangeri (1931) was able to increase the bilirubin content of the blood in animals by injections of blood into the air passages. Bruni (1929) thinks that jaundice in pneumonia should be classified as secondary acquired hemolytic jaundice. Pisani (1930) concludes from a study of 9 cases of visible jaundice in a series of 54 cases of pneumonia that jaundice can be caused by toxic damage to the liver parenchyma, by venous stasis in the liver and by increased hemolysis and also by angiocholitis due to penetration of pneumococci to the bile ducts. Cases of jaundice due to the last cause have been recorded by Lemierre and Abram (1910) and by Ardm Deltel (1909). Jaundice may also be due to causes unassociated with pneumonia and, indeed, a case has been recorded (Lambert and Secretan 1932) in which it followed pneumonia and was due to an aneurysm of the hepatic artery pressing on the common bile duct. Harris (1927) using dye tests showed that high temperature itself did not influence liver function and concluded that liver insufficiency in pneumococcal pneumonia was due to an accompanying toxæmia which damaged the liver. There was no alteration in liver function in advanced phthisis indicating that structural changes in the lungs did not play a part in producing liver inefficiency.

Anyone who sees many cases of pneumonia knows that cases with jaundice fall into two clinical groups—first, those in which the jaundice is slight and of no particular importance, and secondly, those in which it may herald a fatal issue. In a recent paper Coope, Osborn and Pygott (1936) concluded that while some patients with pneumonia could suffer

some liver damage and yet survive, nevertheless an increase of bile in the blood stream did indicate a disturbance of liver function with a worse prognosis. Alexander (1927) says—

"A slight degree of jaundice often exists and is of no particular importance. When jaundice is marked it has been stated by many observers that it indicates a bad prognosis. It is usually due to a duodenal catarrh leading to obstruction of the bile duct, but it is possible that in some of the most severe cases the jaundice is dependent upon the hæmolytic action of the pneumococcus. Unfortunately very little treatment is available in the latter type of jaundice."

In the present paper I am concerned chiefly with jaundice of serious nature. Such cases are recognised clinically by the associated symptoms of cholemia and not by any special laboratory test. The clinical picture of cholemia is not very clearly defined in pneumonia since it is complicated by the symptoms of the causal condition.

In diseases primarily affecting the liver such as acute necrosis the first symptom of cholemia or failure of liver function is usually intense malaise. The patient is irritable and later apathetic. His skin is dry and muddy. The pulse rate rises and there may be slight pyrexia, then anorexia, vomiting, jaundice, and constipation appear. In the final stage the patient is incoherent and delirious and has a subnormal temperature. Convulsions may occur. Sometimes there is air hunger from acidosis, and also diarrhoea and tympanites. Leucine and tyrosine crystals may be found in the urine after alkalisation. Hæmatemesis may occur, and the general hæmorrhagic tendency associated with acute destruction of liver tissue has been called "pseudo hæmophilia hepatica" (Whitby and Britton 1935).

PATHOLOGY

It is well known that the liver is susceptible to many toxins and that its cells are very prone to show necrosis. In acute infectious diseases such as pneumonia cloudy swelling is an early change. In severe infections including pneumonia actual necrosis of liver cells occurs. Hurst and Simpson (1934) described a boy suffering from a myopathy who died of broncho pneumonia complicated by jaundice. The histological changes in the liver were cloudy swelling and slight fatty changes, and in addition parietal zonal necrosis showing swollen granular cells containing karyolytic and pyknotic nuclei. Autolytic changes occur rapidly in the liver after death but in some cases of uncomplicated pneumonia in which it was possible to examine the liver within a few hours of death and in which autolytic changes were minimal definite necrotic changes were found. When severe jaundice complicates pneumonia therefore we may assume that some hepatic necrosis is present.

TREATMENT

Although the outlook in cases of cholemia is usually considered to be hopeless I think that there is reason for not adopting a fatalistic outlook. Under treatment recovery may occur and the essential points in such treatment are the administration of glucose, insulin and calcium, plus measures to combat circulatory failure.

Glucose—The administration of glucose in liver disease is a well established form of treatment, since it is known that the liver parenchyma is protected, if incompletely, from the action of toxins when it contains a good store of glycogen. Davis and Whipple (1919) proved that the immediate nutritional state influenced the effect of potential liver poisons by

showing that the destructive action of chloroform on the liver was intensified by previously with holding food. Newman (1928) showed that a series of cases in which jaundice followed chloroform administration had all been prepared for operation by starving and purging.

In order to protect the liver glucose should be given in large doses. Satke (1933) recommends up to 100 c.cm. of a 10 to 20 per cent. solution of dextrose intravenously but even this amount would seem to be too small. Some idea of the amount required may be obtained from the experiments of Mann and Magath (1922). These workers showed that dogs after complete hepatectomy developed twitchings and other evidence of hypoglycaemia which could be relieved by the injection of glucose at the rate of 0.25 g. per kg. body weight per hour. A patient with severe cholemia is comparable to a dehepatised animal and if he weighed 70 kg. he would need on the basis of 0.25 g. per kg. per hour 620 grammes of glucose in 24 hours.

If the patient is able to swallow it is easy to administer large amounts of sugar by mouth in the form of fruit drinks and barley sugar. It is difficult to give much glucose by the rectum since solutions which are hypertonic—i.e. stronger than 5 per cent.—are absorbed with difficulty and cause irritation. In very ill patients glucose must be given parenterally and this is best done by the intravenous injection of a 30 per cent. solution warmed to body temperature. If pure dextrose is dissolved in distilled water and autoclaved for twenty minutes it can be given quite safely by the intravenous route. It is true that such a solution has been used to cause thrombosis of varicose veins but there is no danger of thrombosis in the arm if some normal saline is injected before removing the needle. In the case described below no symptoms occurred which could be attributed to lowering of intracranial tension by the hypertonic glucose.

Dextrose given intravenously immediately raises the blood sugar above the renal threshold and hence some dextrose is lost in the urine. MacLachlan, Kastlin and Lynch (1932) found that patients with acute lobar pneumonia could be given 25 per cent. glucose in normal saline continuously by the intravenous method and that it was utilized at the rate of 50–60 g. per hour. If it was given slowly enough no glucose appeared in the urine. Incidentally the above workers concluded that glucose was of no value in the treatment of pneumonia and if this is true any good effects in cases of pneumonia with jaundice must be ascribed to its ability to combat the liver condition.

Wilder and Sansum (1917) found that if glucose was given intravenously at a rate more rapid than 0.35 g. per pound body weight per hour some was excreted in the urine. This would allow a ten-stone man about 166 c.cm. of 30 per cent. glucose per hour. This slow rate of injection is not always practicable and I have found that in normal persons not more than 5 g. of a total amount of 50 g. in 30 per cent. watery solution given intravenously at a rapid rate are lost in this way. More is probably lost in patients with liver disease but not sufficient to vitiate this form of administration.

Insulin.—Experimental work concerning the effect of insulin on the carbohydrate metabolism of the liver is somewhat contradictory. It seems probable, however, that insulin favours the storage of glycogen in the liver when plenty of dextrose is available. It has been shown that glycogen will accumulate in the livers of dehepatised dogs but that the rate of glycogen formation is greatly accelerated if insulin

is given and it is probable that the deposition of liver glycogen is in large part due to the action of insulin. Umber (1922) used insulin and glucose in 38 cases of subacute yellow atrophy with 4 deaths. In one case a biopsy of the liver was performed and showed swollen pale granular liver cells containing bile-pigment and fat globules in the Kupffer cells. Icterus was severe and death seemed imminent. Thirty units of insulin twice a day and a rich carbohydrate diet were followed by a cure.

Calcium.—Milot and Cutler (1929) were able to produce acute hepatic insufficiency in dogs by the administration of carbon tetrachloride and the toxic manifestations shown by the animals closely resembled those of cholemia in human beings. They also showed that dogs could be protected against the effect of carbon tetrachloride by the administration of calcium and also that dogs with early symptoms could be cured by calcium therapy. They concluded that, while it was improbable that the pathological lesions caused by the continued action of hepatic poisons could be prevented by calcium, acute hepatic intoxication was unquestionably beneficially influenced by calcium. Cantarow (1933) says he has used calcium therapy in two patients with subacute yellow atrophy with brilliant and dramatic results. He recommends 10 c.cm. of 10 per cent. calcium gluconate intravenously. The following are the details of a case of cholemia complicating lobar pneumonia treated by glucose, insulin and calcium. The rarity of the condition and consequent lack of opportunity for further trial prompts me to record the details of treatment of a single case.

CASE RECORD

A man aged 44, a taxi-driver by occupation was admitted to hospital on Dec. 9th 1933 having been ill for four days with chills and pains in the left chest. Temp. 100 F., respirations, 32, pulse rate 120; blood pressure 160/80. Pleural friction heard in the left axilla and ample evidence of consolidation at both bases. On the 10th 300 c.cm. of air was injected into the left pleural cavity with rapid relief of pain. On the 12th slight jaundice appeared. He was given 250 c.cm. of 30 per cent. glucose and 50 units insulin intravenously. On the 13th he was deeply jaundiced. The temperature had fallen to 98 F. by lysis. The pulse rate was about 110 and regular. Blood pressure 110/60. The heart sounds were distant. There was no evidence of fluid in the pleural sacs. He was in a state of constant delirium. The van den Bergh reaction was prompt direct positive. Bile-pigment and salts were present in the urine and the faeces were coloured. Another intravenous injection of 250 c.cm. of 30 per cent. glucose and 50 units insulin was given.

On Dec. 14th he appeared moribund. He vomit a little and was comatose. The general appearance and odour were those usually associated with drug patient. The odour may have been the fetor hepatis described by the old clinicians. On this day he received two intravenous injections of 500 c.cm. of 30 per cent. glucose with 100 units insulin and 10 c.cm. of 10 per cent. calcium gluconate intravenously. He also had five intramuscular injections of 17 c.cm. Coramine. On the 15th he seemed a little better though jaundice was still marked and he was comatose for long periods. At 2.30 p.m. he received 250 c.cm. of 30 per cent. glucose and 50 units insulin intravenously and at 10.30 p.m. 40 c.cm. of 30 per cent. glucose and 50 units insulin and 10 c.cm. of 10 per cent. calcium gluconate intravenously.

On Dec. 16th he was much delirated and showed evidence of circulatory failure and was given 500 c.cm. of 5 per cent. glucose in saline from a Crookes ampoule. At 8 p.m. 400 c.cm. of 30 per cent. glucose and 50 units insulin were given intravenously. He was extremely drowsy and seemed to be dying. Sugar was present in the urine. On the 17th he received a total of 1000 c.cm.

of 30 per cent glucose and 120 units insulin intravenously. On the 18th he seemed better and again received intravenous injection 600 c cm of 30 per cent glucose and 200 units insulin. On the 19th he was able to take 500 c cm of 30 per cent glucose diluted in lemonade by mouth during the day. On the 20th he refused 30 per cent glucose by mouth but took about 500 c cm of a 10 per cent solution of glucose in 0.5 per cent sodium chloride iced and flavoured with lemon juice. He was also given 420 c cm of 30 per cent glucose and 100 units insulin intravenously.

On Dec 21st he was given 360 c cm of 30 per cent glucose and 100 units insulin intravenously. By this time he was very much improved and no further intravenous injections were given. He was able to take small amounts of food by mouth. He was seriously dehydrated and took considerable quantities of the glucose saline drink. The jaundice gradually disappeared. He was discharged on Feb 15th, 1934, after a stay of nine weeks.

On Jan 9th, 1934, the lavalose tolerance test was carried out. The fasting blood sugar was 126 mg per 100 c cm. Fifty grammes of lavalose was given by mouth, and after one hour the blood sugar was 144 mg and after one hour it had fallen to the fasting level indicating a normally functioning liver.

The accompanying Table shows the amounts of glucose, insulin, and calcium used.

Table showing Treatment

Date in Dec	Glucose intra venous, 30 %	Insulin in units	Calcium gluconate, 10 %	Other treatment
	c cm		c cm	
12th	250	50	—	—
13th	250	50	—	—
14th	560	100	10	—
	560	100	—	—
15th	250	50	—	—
	540	50	10	—
16th	400	60	—	560 c cm 5% glucose in normal saline intra venously
17th	300	60	—	—
	300	60	—	—
18th	300	100	—	—
	300	100	—	—
19th	—	—	—	500 c cm 30 % glucose by mouth
20th	420	100	—	—
21st	360	100	—	500 c cm 10 % glucose by mouth
Total	4790	980	20	—

A single example can never be used to prove the value of any form of treatment and every clinician has seen apparently hopeless cases recover. A nihilistic attitude in such cases is not justified and while it is impossible to be sure that death would have occurred without the treatment used or to refute the view that recovery would have occurred without any treatment, I suggest that the treatment used had a beneficial effect.

SUMMARY

The causation of jaundice complicating pneumonia is discussed. The theoretical reasons for treating jaundice and cholemia with insulin, glucose, and calcium are stated, and a case is reported in which such treatment was successful.

I am indebted to Mr Ivor Lewis, medical superintendent of the North Middlesex County Hospital, for permission to publish the notes of this case.

PERNICIOUS ANÆMIA IN AN INFANT

By F S LANGMEAD, M.D., F.R.C.P. Lond.

PROFESSOR OF MEDICINE UNIVERSITY OF LONDON AND

I DONIACH, M.D. Lond.

ASSISTANT PATHOLOGIST DEPARTMENT OF PATHOLOGY,
ST MARY'S HOSPITAL

THE existence of pernicious anæmia in infancy is disputed by many authorities for it is difficult to find authentic cases and it does not fit in with the present concept of the etiology of this disease. The question arises whether there is any place for liver therapy in the primary anæmias of early life. Bachman (1936) has recently reported a case of macrocytic hyperchromic anæmia in an infant and reviewed 16 similar cases described since 1909. The recent cases were quickly cured by liver and remained well without any further treatment. Laboratory investigations showed that the majority had a normal icterus index and low gastric acidity. There was a history of infection in most of the infants. He put forward the view that the cause was dietetic combined with a low gastric acidity due to infection. His own case, an infant nine months old with a previous otitis, had a blood count with a colour index of 1.11, the hemoglobin being 83 per cent. The icterus index was normal, the stomach secreted only a little acid in response to histamine. Liver treatment brought about a reticulocyte response of 8 per cent, and when a normal blood picture had been restored the free acid in the stomach rose to within normal limits.

Parsons and Hawksley (1933) gave the following criteria for the diagnosis of pernicious anæmia in childhood: "In addition to megalocytosis there should be a high indirect van den Bergh, marked poikilocytosis, almost always an absence of free hydrochloric acid in the gastric juice, and a reticulocytosis with liver extract." The case described below fulfils these criteria.

CASE REPORT

The patient, aged 13 months, was admitted to the medical unit at St Mary's Hospital in October, 1936. He had been vomiting for three weeks, and he was under weight and backward in development. He was very ill and looked as though he was going to die. Weighing 6½ lb at birth he had been breast fed until 7 months old, from then till 13 months he was fed on diluted cow's milk with the addition of white bread, orange juice and two teaspoonfuls of Virol a day. His first teeth erupted at 7 months and he sat up at the same period. He has

one brother and two sisters all in good health. His mother thought that he was a dull baby compared with her others. His parents and grandparents are alive and well.

On examination the infant had an extreme waxen pallor. His heart was considerably dilated a widespread systolic murmur being heard in the chest maximal at the lower end of the sternum. The veins in the neck were engorged, the liver edge was palpable halfway between the costal margin and the umbilicus, and the spleen could be easily felt. The anterior fontanelle was widely patent and showed much pulsation.

Laboratory investigations.—The icterus index was 17.8 units. The Wassermann reaction of the blood was negative. There was no occult blood in the faeces. An examination of the stool for fats showed total fats 35.0 per cent soaps 28.4 per cent fatty acids 3.5 per cent neutral fats 3.7 per cent. There was no free acid in the gastric juice. A blood count showed—

Red cells	2,550,000	Leucocytes	8,000
Hemoglobin	30%	Polymorphonuclears	20%
Colour index	0.98	Lymphocytes	68%
		Large mononuclears	1%
		Eosinophils	0%
		Basophils	0%

The red cells showed marked anisocytosis and poikilocytosis they were strongly eosinophilic with but slight polychromasia. One nucleated red cell was seen in the film. The polymorphonuclears had many lobes to their nuclei and platelets were almost absent from the film. The reticulocyte percentage was 1.3.

These results suggested that the child was suffering from an anemia due to lack of the hemopoietic principle.

Treatment and progress.—In view of his extreme illness we did not experiment and he was given liver extract rather than any preparation containing Castle's extrinsic factor. He was treated with intramuscular injections of Campton (2 c.c. every day). This resulted in a reticulocyte response of 18 per cent and a clinical improvement. A blood film taken at the time showed considerable polychromasia and 3400 nucleated red cells per c.m. Iron was added to his diet in the form of iron and ammonium citrate gr 3 three times a day. The blood count rose within a month to 5,000,000 red cells and 90 per cent hemoglobin, the colour index being 0.9. The

FIG. 1.—Chart showing reticulocyte response to campton and progress of the patient in hospital. RETIC.—reticulocytes. R.B.C.—red blood cells. Hb.—hemoglobin.

film showed numerous platelets, an increase of eosinophils and slight anisocytosis and poikilocytosis of the red cells. The improvement was maintained the child putting on over 3 lb in three months. He was given a mixed diet including marmite and orange juice. The course was however slightly marred by attacks of coryza. Fig. 1 represents the blood counts in chart form and shows his response to treatment. There was no free hydrochloric acid secreted in the gastric juice in response to an injection of histamine three months after the patient had been in hospital. The blood count at the time was normal and the patient was discharged.

DISCUSSION

A Price-Jones curve (Fig. 2) was drawn from a film taken before any treatment had been instituted.

The megalocytosis and microcytosis the values of σ and ν resemble the pernicious anemia curve seen in the adult. As a result of his age and gastric acidity it is reasonable to suppose that the child's iron storage was deficient. The hyperchromic anemia was probably superimposed upon a previous microcytic iron deficiency anemia of infancy. The mean diameter of 7.4 μ in the Price Jones curve may well have been a shift to the right of 1 μ from a previous

FIG. 2.—Price-Jones curve before treatment began.

6.4 μ . Castle and Minot (1936) state that the typical macrocytic blood picture of pernicious anemia may be modified by the presence of a complicating deficiency of iron to a normocytic or mildly hypochromic type. It will be interesting to see whether the patient remains well without liver therapy or whether he will need liver for the rest of his life.

The case appears to be one of pernicious anemia in an infant modified hematologically by a probable initial iron deficiency by virtue of the patient's age and deficient gastric acidity. One of the most striking features of the case was the excellent reticulocyte response to liver treatment.

SUMMARY

A case of pernicious anemia in an infant is described which fulfils the criteria of Parsons and Hawksley for this diagnosis in that his anemia was hyperchromic with a megalocytosis of 68 per cent, his icterus index was 17.6 units, his red cells showed considerable poikilocytosis, he secreted no free hydrochloric acid in response to histamine and he had a reticulocyte response of 18 per cent to campton when his red cell count was 2,000,000 per c.m. He was treated with liver and iron and discharged from hospital clinically well and with a normal blood picture.

We wish to thank Dr W. F. Henley, assistant to the medical unit who has carried out the chemical investigations.

ROYAL HOSPITAL, WOLVINGTON.—Expenses at this hospital during the last year have increased but contributions have kept pace with them. New extensions are proposed consisting of a semi-basement and three storeys planned so that in the future two or three more storeys can again be added if required. The semi-basement is to be made into a swimming bath and a gymnasium for the nursing staff and resident officers and the first two floors will each accommodate thirty beds.

RELAPSING STAPHYLOCOCCAL
SEPTICÆMIAASSOCIATED WITH CIRRHOSIS OF THE
LIVER AND SPLENOMEGALY

By F A PHILLIPPS, M D Camb

AN ÆTHETIST TO THE EVELINA HOSPITAL FOR CHILDREN
LATE SENIOR CLINICAL ASSISTANT TO THE HOSPITAL
FOR SICK CHILDREN

THE following case appears to me to be of considerable interest, and I therefore venture to report it. The patient, a well developed man aged 29, serving in the Navy, had severe jaundice, which varied considerably during the period of observation.

HISTORY

When at Dartmouth in 1922, at the age of 15, he was told that he had a thrill in his pulmonary artery and was not allowed cross country runs, though he played all games, including rugger, squash, &c 1927 had a febrile illness associated with hæmaturia, radiograms negative for stone. December, 1928 in Mediterranean, sent to Naval Hospital at Malta, diagnosed as rheumatic fever hand, elbow, shoulder, and right arm only affected, profuse sweating. March, 1930 kick on right shin at rugger, abscess followed, which was drained and healed quickly. 1932 at this time he was first noticed to be yellow.

Apparently from 1930 to 1933 he was playing rugger, squash, tennis, &c, and was in good health. August, 1933 in sick quarters at Shotley pain right shoulder, temperature 99° F treated with salicylates. September transferred to R N Hospital, Chatham, very yellow in face, and right shoulder very painful, negative reaction to test for tuberculosis, right shoulder immobilised, pyrexia. Prolonged sick leave on account of stiff shoulder. August, 1934 febrile attack. January, 1935 again injured right shin, again with abscess formation. March febrile. October in hospital at Aden, febrile for a few days yellow.

He was apparently afebrile from October, 1935, to March, 1936, having treatment for stiff right shoulder. March, 1936 right arm manipulated, he became much more jaundiced. April he started gastric symptoms—"indigestion," pains after meals, jaundiced.

There was no history of alcoholism or venereal disease.

EXAMINATION

The liver, which was not enlarged, was easily palpable below the costal margin. The spleen was enlarged and hard, and descended to the level of the umbilicus. There was a rough systolic murmur maximal over the left inter costal space, with well marked clubbing of the fingers. No Osler's nodes were observed. He had old arthritis of the right shoulder for which massage and mild movement had been given. The humerus could be moved some 30° before movement of the scapula was evident. No pain, heat, or swelling was present in the shoulder joint, but all muscles were wasted and deltoid movement was very limited. The abdomen was somewhat distended, which was in part due to the splenic enlargement. Old scars were present on the right shin.

INVESTIGATIONS

Van den Bergh reaction—June 20th positive and direct 5.0 units. Icteric index 30.

Urine (Dr W J Griffiths)—Urobilinogen not increased. bile a trace, bile salts absent. Centrifuged deposit shows neither red cells, pus cells, nor casts.

Blood examination (June 29th Dr J Bamforth)—

Red cells	3 840 000	Leucocytes	5900
Hæmoglobin	50%	Polymorphonuclears	60%
CI	1.04	Lymphocytes	33%
(confirmed by repetition)		Eosinophils	0.5%
No malarial parasites		No abnormal leucocytes	2%

July 1st platelets, 180,000 per cm, reticulocytes, 2.4 per cent.

Serum found to be jaundiced. Sachs George reaction negative. Agglutination against *Brucella melitensis* and *abortus* was negative in all dilutions. Fragility of red cells, hæmolysis started at 0.4 per cent (slightly more resistant than normal).

TREATMENT AND PROGRESS

At this period he was given Pernammon Forte 5.0 cm intramuscularly twice a week with ferri et ammon cit gr 20 tds, p.c. per os.

After his return home he continued to suffer from attacks of pyrexia at approximately fortnightly intervals, the temperature varying from 104° F on occasion to 100°, the usual duration being for two or three days. The first of these attacks occurred in May, 1936, from which time they recurred throughout the course of the illness.

Blood examination—On July 5th Dr W C Carnegie Dickson made an examination of the blood during a pyrexial attack, the count of which did not differ materially from the previous one of Dr Bamforth's, the colour index being 1.3, polymorphs 78.3 per cent. There was a moderate degree of anisocytosis with general increase in size to 9 or 10 μ , no appreciable poikilocytosis, no nucleated corpuscles or polychromasia. No malarial parasites, spirochetes, or kala azar parasites were seen. Severe leucopenia, eosinophils absent, blood platelets scanty. *Brucella* and *abortus* negative, fragility normal. Wassermann reaction negative. Gonorrhœa complement fixation, slightly more deviation than with normal.

Urine—(non catheter specimen) on ordinary agar, blood agar, &c, a growth of *Staphylococcus aureus*, in fluid media a very occasional streptococcal chain.

Blood cultures—Primary cultures and a series of sub cultures at 16 and 26 hours showed no growth, but at 50 hours showed a pure growth of *S. aureus*. These cultures were made during a febrile attack, two cultures made on the 6th (pyrexia subsided) showed no growth at 56 hours.

Van den Bergh reaction—Positive immediate direct, indirect also well marked (25 mg per litre of serum).

Sedimentation test normal.

Consultation—On July 17th the patient was seen by Sir Maurice Cassidy, Prof J W McNee, and Dr P Manson Bahr in consultation, when the question of tropical disease was fully discussed and eliminated. As a result of these deliberations cholecystography and a levulose-tolerance test were carried out. At the same time a radiogram of the great trochanter of the left femur was taken, as persistent pain was complained of with slight swelling.

Radiography—The cholecystography, by Dr W H Coldwell and Dr F M Allchin, was completely negative as dye did not enter, while the femur showed a small area of rarefaction with a sequestrum in its centre.

Levulose test (Dr Griffiths, July 27th). The blood sugar curve after 30 g of levulose was, within the accepted limits of normality, as follows—

Before test	0.117%	90 mins	0.117%
30 mins	0.135%	120	0.109%
60	0.139%		

A further blood count showed little difference from the previous ones, but the colour index was 0.9.

During the months of August and September the patient continued to receive injections of pernæmon once a week. He showed some slight improvement as evidenced by diminution in size of the spleen, less jaundice, and a lowered height of pyrexia in the attacks.

On Oct 17th, although he was not feeling well, he went out to dinner, and during the night developed a temperature of 103° F with gastric symptoms which persisted, and on Oct 21st he was transferred to St Thomas's Hospital for further investigation.

A blood count (Dr Bamforth) on this date showed red cells 25,400,000, hæmoglobin, 56 per cent, colour index, 1.09 per cent, leucocytes, 5600. Reticulocytes very scarce—not more than 1 per cent. Fragility of red cells started just below 0.4 per cent (more resistant than normal). No eosinophils in 200 leucocytes counted. A number of red cells showed polychromasia and a few cells showed basophil stippling, both constituted a small percentage of the cells.

Blood cultures taken on the same date gave numerous colonies of *S. aureus* in pure culture while cultures of the sputum on Oct 22nd gave an overwhelming growth of the same organism. On Oct 24th and 26th he received intravenous injection of 40 c.c.m. of staphylococcal anti-toxin daily after a preliminary testing with 0.1 c.c.m. and on Oct 25th 2 c.c.m. of parameon forte. The rest of the treatment was symptomatic.

The patient's pyrexia persisted, the jaundice markedly increased and he died on Oct 27th in coma.

POST MORTEM EXAMINATION (DR. J. O. OLIVER)

Diseases.—Staphylococcal septicæmia, osteomyelitis and cirrhosis of liver. Examined Oct 27th, 1936. Age 30.

Weights of body and viscera.—Liver 5 lb. 10 oz. Kidneys left 17½ oz. right 17 oz. heart 17 oz. spleen 2 lb. 12 oz.

Report.—There was a quantity of slightly blood-stained fluid in the abdominal cavity. Straw-coloured fluid distended the pericardial sac. Large numbers of firm adhesions were present all around the gall bladder and the main biliary duct.

The liver showed an extreme degree of multilobular cirrhosis with dilatation of all the larger bile channels of the liver. The gall bladder itself was distended with concentrated bile. There did not appear to be any obstruction of the bile-ducts other than that which might be accounted for by the adhesions referred to above.

The heart was grossly dilated on the right side and on the left side generally hypertrophied. A minute opening was present at the position of the foramen ovale and this opening was valvular in type suggesting a possible passage of blood from the left to the right side of the heart.

There was a small pyramic abscess in the wall of the aorta about 1 in. above the aortic valve and this had ruptured into the aorta itself.

The left lung was semi-collapsed with some exudate at the base and a number of small pyramic abscesses scattered throughout the lungs. The right lung was congested and oedematous.

The kidneys were extremely large and showed many small pyramic abscesses running along the course of the blood vessels.

The spleen was large and showed some septic reaction in an organ which appeared to have been previously enlarged.

The left femur a small superficial softened area was found in the bone in front of and below the great trochanter.

The brain showed congestion and oedema only. The sinuses showed no apparent infection in the ethmoid or frontal cells.

There was no macroscopic thrombosis of the splenic or portal veins.

A photomicrograph of a part of the liver is shown in the Figure and Prof. McNece has kindly given me his opinion of the section. This slide shows very typical advanced cirrhosis in a fairly active stage with much round celled infiltration.

Typical advanced cirrhosis in a fairly active stage

COMMENT

Some points of particular interest in this case appear to be as follows: 1 The prolonged duration probably a period of 8 years with intermittent exacerbations of a staphylococcal infection. 2 The association of the above with multilobular cirrhosis of the liver and considerable splenic enlargement. 3 The uniformly high colour index. 4 The normal kaovulose test in spite of the advanced cirrhosis. 5 The presence of a pyramic abscess in the wall of the aorta.

My thanks are due to the many doctors who have carried out the numerous investigations for the use of their notes, and especially to Sir Maurice Cawley for his kind criticisms and help with this report to Prof. J. W. McNece for his opinion on the slide and to Dr. J. O. Oliver for his account of the findings at autopsy.

CLINICAL AND LABORATORY NOTES

ACUTE SACRO ILIAC STRAIN

A PERSONAL EXPERIENCE

By R. Y. PATON, M.B. Camb. F.R.C.S. Eng.

ORTHOPEDIC SURGEON, ROYAL ORTHOPEDIC HOSPITAL, CONVENT ROAD, LONDON, E.C.1.

As I was digging in my garden the other morning and endeavouring to turn over a particularly resistant portion of clay soil I experienced a sudden acute pain in the lower part of my back on the right side and on trying to straighten myself up was unable to do so.

It was with difficulty that I was able to walk a few yards to the house and with even more difficulty to ascend the few steps necessary. Walking was extremely painful and I could do so only with the right hip and right knee slightly flexed. On sitting down I found it very hard to get into a comfortable position and impossible to cross the right knee over the left without great pain. There was great tenderness over the upper portion of the right sacro-iliac joint and there was pain down the back of the right thigh and on the outer aspect of the right calf. Ten grains

of aspirin made not the slightest impression on the pain. When the telephone rang it was with great difficulty that I lowered myself out of a chair and walked the few feet to it.

After about an hour the pain was still as bad, so I thought I must attempt some form of self-manipulation as I had relieved so many people in similar conditions by manipulation. I stood up as straight as I could with my legs abducted and my feet externally rotated. With my arms widely abducted I rotated my trunk towards the left and then suddenly, and as vigorously as I could, rotated my trunk round to the right as far as it could go. There was a sudden audible snap and the pain down the leg had completely gone. I was able to move perfectly freely again; I returned to the garden and completed my digging and then I proceeded to pull a heavy roller all over the lawn without any discomfort or disability. The next day, apart from a slight ache in the right sacro-iliac region, there were no other symptoms whatsoever and all movement being perfectly free and painless.

Cases of acute sacro-iliac strain are common and their relief by manipulation is well known. The customary manipulation is to rotate the pelvis forwards with the shoulders fixed at the same time using some downward pressure on the pelvis. This man-

pulation can be done easily without an anæsthetic if the attack is of very recent onset, but later requires a general anæsthetic. The movements which I carried through in my own case were intended to reproduce this rotary movement as far as possible, and results show that they were successful.

I hope this small note will prove of use to any medical colleague who finds himself similarly smitten.

PULMONARY ŒDEMA FOLLOWING THE ADMINISTRATION OF ESERINE

By W. E. COOKE, M.D. Liverp., F.R.C.P. Lond. and Edin., D.P.H.

DIRECTOR OF THE PATHOLOGICAL DEPARTMENT, WIGAN INFIRMARY

THE increasing frequency in the use of eserine in renal sympatheticonus as well as the unusual fatality prompt this note.

A female, aged 19, was operated upon for subacute appendicitis in August, 1936. In January, 1937, she returned to Mr. J. B. Oldham with right renal colic. During the renal investigations it was noticed there was definite delay in the emptying of the right renal pelvis.

and the condition was diagnosed as renal sympatheticonus. Immediate renal sympathectomy was considered unjustifiable, the patient sent home and her family doctor advised to inject 1/50 of a grain of eserine if attacks of colic recurred. She resumed her occupation, apparently well, until March 6th, 1937, when returning from work she had an attack of pain in the right flank. She walked into her doctor's waiting room and lay on a couch. One-fiftieth of a grain of eserine was administered hypodermically. In a few seconds the patient was seized with intense respiratory distress, becoming increasingly urgent, and blood stained frothy mucus poured from her mouth. She was given 1/100 of a grain of atropine but she died in about fifteen minutes after the eserine injection.

Autopsy.—The pupils were midway between contraction and dilatation. There was a band of adhesions anchoring the cæcum to the anterior abdominal wall. The pelves of both kidneys were injected and the bladder contained a little purulent urine. The larynx, trachea, and bronchi contained blood stained frothy mucus. The lungs were voluminous and heavy, pitted on pressure, and on section poured out blood stained serum. All the other organs were normal.

The above are the facts of the case, and comment seems unnecessary unless it is to point out the possible untoward effects of eserine and that, although atropine was administered, the course of the pulmonary Œdema remained unchecked.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE

SECTION OF UROLOGY

THIS section held its annual general meeting in London on April 22nd and 23rd under the presidency of Mr. BERNARD WARD (Liverpool).

Closed Prostatectomy

Mr. CLIFFORD MORSON opened a discussion on the Harris operation and its modifications. The most important modification that he himself had introduced was the substitution of a longitudinal for a transverse incision, and the elimination of the postero-lateral sutures in the reconstruction of the bladder base. He objected to such sutures because of their nearness to the ureteric orifices. For Harris's lateral sutures he substituted a figure of eight suture which he believed to be more effective in closing the cavity. Only if the urine was not sterile or if he was dissatisfied with the hæmostasis did he omit primary closure of the bladder. Mr. Morson then gave his reasons for preferring the Harris to all other techniques in prostatectomy. He did not wish to justify it simply because of the mortality rate—for mortality rates were deceptive unless at least 500 operations had been done—but because it eliminated many of the dangers and complications following prostatectomy, shortened the period of convalescence, and added to the patient's comfort. Both reactionary and secondary hæmorrhage were uncommon after it, and the stay in hospital was reduced by at least a fortnight. Moreover the Harris technique diminished what he termed the remote mortality of prostatectomy—i.e., deaths occurring some six months after the operation as a result of the strain to which patients had been subjected.

Mr. W. W. GALBRAITH (Glasgow) stated that in 27 out of 29 cases he had closed the bladder. In his opinion some of the opposition to the Harris technique was due to the fact that the principles laid down by Harris were not followed, especially was this true of preliminary treatment. But the

fact that he, Mr. Galbraith, favoured the technique did not mean that he felt that it should be carried out in every case. Selection was necessary, and in this selection the state of the cardiovascular system was of very great importance.

Mr. TERENCE MILLIN said that the chief modification he had made in the original Harris technique was to substitute Lumbe's method of bringing down the posterior trigonal flap for that of Harris. As a precautionary measure he also placed two temporary "funk" silk sutures on the bladder and brought them out of the abdominal wound. If it became necessary to open the bladder because of hæmorrhage, the sutures made this easier.

Mr. C. A. WELLS (Liverpool) advocated the transverse incision employed by Harris, because he felt that it encouraged better healing. As a safety valve he used a small suprapubic tube closed by a spigot. Through this the bladder could be washed out if need be.

Mr. A. H. JACOBS (Glasgow) was surprised that no speaker had mentioned that severe complications might follow the Harris technique. He himself had had two cases of serious pelvic cellulitis. In one of these the patient had died and post mortem an abscess was found posterior to and communicating with the prostatic cavity. This did not mean that he would not employ the Harris technique, but he felt it necessary to point out that its complications might be more serious than previous speakers had suggested.

Mr. MORTON WHITBY called attention to the importance of pre-operative treatment. He had devised a two-way catheter by means of which continuous irrigation might be carried out.

Mr. E. W. RICHES preferred a transverse to a longitudinal incision on the ground that his patients' comfort was thereby increased and convalescence shortened. Cases must be selected for the Harris operation, and he thought that when death occurred it was usually due to some systemic cause such as embolism or cardiac failure. As an anæsthetic he

liked a combination of a low spinal analgesia followed by gas and oxygen with an abdominal field block.

Perurethral Operations

Mr KENNETH WALKER read a paper on the treatment of prostatic obstruction by perurethral methods. He recalled that he had introduced a similar discussion as long ago as 1926. His mode of presentation would however be very different on this occasion. In 1926 it was necessary to plead for a method that was in its infancy—and in a none too healthy infancy. Now the child had grown so lusty and rampagous that in some parts of the world it was necessary to plead not for perurethral methods of treatment but for the parent operation of prostatectomy. He would therefore assume the attitude of a critic rather than of an apologist, dealing especially with the complications and disadvantages of perurethral resection. In his experience the main disadvantage was sepsis. Some of this sepsis was inevitable and due to the fact that the operator left behind coagulated tissue which formed an excellent nidus for organisms. Because of this there was a present tendency to turn again in the direction of Young's cold punch using coagulation merely for sealing-off bleeding points. But some of the sepsis was due to the trauma of instrumentation. An electrotome was not an easy instrument to pass and in cases of involution of the genital tract where the urethra was small it was easy to damage the tissues. Another fruitful source of infection was probably opening up the space of Denonvilliers by perforating the trigonum. Mr Walker concluded by discussing what cases were suitable for resection. Perurethral methods were particularly indicated in minor enlargement of the prostate and for patients in whom there were complications that made prostatectomy too dangerous.

Mr R. H. O. B. ROBINSON described the technique employed at the Mayo Clinic. Two instruments were in use there the Bumpus and the Thompson punch. Both instruments were difficult to handle because they were of the direct vision type. They had the advantage however of causing less damage to tissues. He employed these methods at St. Thomas's and with satisfactory results.

Mr F. Mc G. LOUGHRANE called attention to the danger of resecting prostatic tissue on either side of 4 or 8 o'clock. Where he had disobeyed this rule he had had infection of the cave of Retzius.—Mr H. P. WINDSBURY WHITE did not believe in massive resections but in removing only five or six fragments.—Mr MILLIN preferred Young's punch for fibrous prostates because of the danger of pelvic cellulitis. In carcinoma and cases of post prostatectomy obstruction the McCarthy resectotome gave excellent results.—Mr JOHN EVERIDGE recalled a case where in attempting to get the loop above a large lateral lobe in a bladder that could not be distended the wall had been perforated. He said that in order to avoid haemorrhage a cut could not be made too slowly.—Mr RICHES pointed out the advantage of infiltrating the prostate before resection with 0.5 c.c.m. of adrenaline in 10 c.c.m. of Peracine solution. This materially reduced haemorrhage. If clot retention occurred after operation the glycerin of pepsin treatment gave excellent results.

Spinal Injuries and the Bladder

Sir JOHN THOMSON WALKER on April 23rd read a paper on injuries to the spinal cord affecting the bladder. Before the late war he said it was taught that injuries to the lumbar swelling and cauda equina were followed by distension of the

bladder and overflow. Experience during the war however showed that after such injuries periodic reflex micturition was soon established the bladder learning to contract at intervals and to empty itself more or less satisfactorily. The chief problem during the war had been the avoidance and treatment of sepsis 80 per cent. of spinal cases dying of surgical kidney. He would therefore like to discuss how this appalling death rate could be avoided. Four methods of treatment for the retention following spinal injuries were possible.

- (1) Non interference—i.e. allowing the distended bladder to empty itself by overflow.
- (2) Emptying the bladder by abdominal pressure.
- (3) The use of an in-dwelling catheter.
- (4) An immediate prophylactic cystotomy.

The chief disadvantage of non interference was that the rule that a distended bladder should be emptied by the passage of a catheter was so ingrained in the medical profession that during the war it of the wounded from the front to England some doctor was bound to pass a catheter. Emptying of the bladder by pressure on the abdomen could only be carried out by someone skilled in this method of treatment. Spasm of the sphincters made it sometimes very difficult and rupture of the bladder had been reported. The chief complication that had arisen in the war from the use of an in-dwelling catheter was sloughing of the floor of the urethra at the penoscrotal junction. Personally he had advocated immediate prophylactic cystotomy as the best method of overcoming the peril of sepsis. While this did not prevent cystitis it removed the conditions favourable to the upward spread of sepsis—namely infection associated with retention. What was required most in order to solve the problem was continuity not only of observation but also of treatment.

Sir ALFRED WEBB JOHNSON thought that an authoritative statement that a catheter must never be passed in the presence of a spinal injury would save many lives. He suggested that the right combination of treatment might turn out to be non interference at the front and early cystotomy at the base hospital or when the patient reached England.

Mr KENNETH WATKINS (Manchester) confirmed the fact that cases of spinal injuries in civil life did not die of urinary sepsis. This was probably because whereas most civil injuries were injuries to the cauda equina most war injuries were at a higher level.

Mr EVERIDGE described a case of spinal injury in the dorsolumbar region that had been successfully treated by early cystotomy.

Undescended Testis

Prof. GRAY TURNER in a paper on the treatment of the undescended testicle said that up till 1927 he had made very little effort to save a misplaced testicle and had usually performed orchidectomy. Since then however he had adopted a more conservative attitude. He was sceptical about a testicle ever descending spontaneously after the third year of life. Some authorities considered that the best period of life at which to begin hormone treatment was at about nine; he himself was of the opinion that eleven or just before puberty was the time of election for operative treatment. This would allow of patients having a preliminary trial of gonadotropic hormone. In discussing operative technique he laid emphasis on the importance of mobilisation of the cord as high up as possible. The chief obstacle

to a testicle being brought down was not shortness of the vessels but adhesions between the vas and the peritoneum

Mr W McADAM ECCLES urged that the term "undescended testicle" should be abandoned in favour of "imperfectly migrated" testicle. Much had still to be learnt about this subject, and he felt that the greatest help would be obtained from the experience of medical officers to schools.

Mr T W MIMPRISS gave the post operative records of 80 cases treated by the Bevan technique at St Thomas's Hospital. Only half of these operative results could be said to be satisfactory. Better results were noted with the transeptal technique and although there were as yet an insufficient number of cases available, it looked as if the Keetley Thorek technique was going to give the best results of all. He was sceptical of the action of gonadotropic hormone.

Dr RONALD SMITH (Rugby School) said that imperfectly descended testicle was extremely common amongst schoolboys. Contrary, however, to Prof Grey Turner's belief, a very large number of these testicles descended spontaneously before puberty. He therefore recommended that all cases be left till puberty before an operation was undertaken.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY

A MEETING of this society was held in Sheffield on April 2nd with Dr J W BRIDE (Manchester), the president, in the chair.

Labour Obstructed by Fœtal Bladder

Dr F J BURKE (Liverpool) gave an account of a case of dystocia due to over distension of the fœtal bladder.

The patient, a multipara aged 29, went into labour at 9 p.m. on Jan. 27th, being about 35 weeks' pregnant. At midnight the head and hands of the fœtus were born but there was no further progress. When admitted to hospital she was having strong pains and was acutely distressed. The fundus reached to midway between the umbilicus and the ensiform cartilage, and no fœtal heart could be heard. A fœtal head and two hands were protruding through the vulva. The fœtal neck was long and the cervical spine was fractured—no doubt through vigorous traction by a practitioner who had been called in by the midwife. The thorax was found tightly plugged in the maternal pelvis, and an incision was made through the fœtal chest wall. A large quantity of fluid escaped and delivery was soon completed. The fœtus weighed 6 lb and was considerably elongated, with the abdominal wall in large folds; there was also bilateral talpes equinovarus. Post mortem the bladder in its collapsed condition measured 6 in. by 4 in. and had hypertrophied walls. Both ureters were dilated and the kidneys enlarged. The urethra was patent, a small catheter passing without difficulty.

Dr Burke said that several similar cases of distension of the fœtal bladder with patency of the urethra had been described, and he quoted those of Savage and Crawford and Jeffcoate. Neuromuscular dysfunction was the usual explanation of the failure of the fœtal bladder to empty itself. He also wondered what part was played by the fœtal kidneys in the production of liquor amni. Gaylord Bates had pointed out the frequent association of oligo-hydramnios and fœtal renal anomalies. The biochemical studies of Makepeace Smith and Carroll strongly suggested that the liquor amni was a

transudate which, in early pregnancy, was in isometric equilibrium with maternal and fœtal blood, but in late pregnancy was hypotonic because of the addition of fœtal urine. On the other hand, there was evidence that the fœtal kidneys did not subscribe to the liquor amni. Phloridzin injected into the mother could be readily detected in the fœtal tissues, but it was rare to find even a trace of sugar in the liquor amni.

The PRESIDENT said that the condition seemed always to be associated with obstruction to the urethra, and that he supposed it was more common in the male fœtus—Mr J E STACEY referred to the elongation of the cervical vertebra and the talpes equinovarus, and wondered whether the condition was associated with any spinal lesion—Dr BURKE, in reply, said he had no doubt that the elongation of the cervical vertebra was produced by trauma.

Adenomyoma Causing Intestinal Obstruction

Mr A GOUGH (Leeds) described a case in which an adenomyoma was responsible for acute intestinal obstruction.

The patient, aged 42, had never been pregnant. She had had gradually increasing constipation for six months, culminating in complete obstruction. The day before Mr Gough saw her, she had had absolute constipation as regards both faeces and flatus, and had vomited once. Her general condition was quite good, and there was a tense rounded swelling in the hypogastrium the size of a four months' pregnancy. On vaginal and rectal examination a hard fixed mass was felt behind the uterus and involving the upper part of the rectum. On opening the abdomen the rounded swelling was found to be a chocolate cyst of the left ovary. There was much indurated tissue involving the cervix and the upper part of the rectum. A diagnosis of adenomyoma was made, and later confirmed by histological examination. A colostomy was performed, after the bulk of the disease had been removed, including both ovaries and the uterus. A fortnight later, Mr Gough was able to start making a way through the obstructed bowel, by passing gum elastic bougies up the rectum. These were followed later by rectal tubes passed from the colostomy downwards. In a fortnight the passage had been dilated to $\frac{7}{8}$ in. The colostomy was closed in stages by the use of an enterotome. Six days later the bowel was dissected from the abdominal wall and the wound closed. Some leakage occurred but within three weeks the fœcal fistula had closed.

Mr GOUGH said that an acute obstruction due to an adenomyoma must be very rare indeed—The PRESIDENT said it was quite clear that the adenomyoma was in the bowel wall, and not merely in the rectovaginal space—Prof LEYLAND ROBINSON (Liverpool) remarked that the case showed how important it was that a gynaecologist should have a knowledge of general surgery.

Dr GLADIS KAY gave a demonstration of X ray films taken of pregnant women during the ante-natal period. The PRESIDENT, Prof A M CLAYE (Leeds), Mr J E STACEY (Sheffield), and Mr T F TODD (Manchester) took part in the discussion.

SALFORD ROYAL HOSPITAL.—Extensions and alterations to this hospital though not quite finished were opened on April 12th. The ceremony took place in the new Bernhard Baron orthopaedic department, for which the trustees of the late Mr Baron have given the sum of £3000. The erection of a new casualty department and the enlargement of the outpatients accommodation have been made possible by a donation of £8000 from the Lancashire and Cheshire Miners' Welfare Fund. The hospital's deficiency on capital account now stands at £24,498.

REVIEWS AND NOTICES OF BOOKS

Diseases of the Nose Throat and Ear

A Handbook for Students and Practitioners By I SIMSON HALL MB ChB FRCP E FRCS Surgeon to the Royal Infirmary Edinburgh (Department for Diseases of Nose Throat and Ear) Edinburgh E and S Livingstone 1937 Pp 422 10s 6d

Mr Simson Hall has tried to explain the essential features of disease of the throat, nose and ear within the compass of a very small book intended for the student and the busy practitioner. It is due to the clearness of his thought and style that he has achieved a considerable measure of success, though the result would have been still better had he allowed himself a little more space. A very short account of the anatomy of the region is given before each section and the usual methods of examination are described. But in many cases the picture presented of the commoner clinical types of a disease is not adequate to enable the practitioner to recognise it and make a diagnosis. This is especially notable in the section on diseases of the larynx where the description of tuberculous laryngitis can give the reader no idea of its usual aspects. The flask-shaped arytenoids, turban epiglottitis and the early unilateral infiltration of the cord are not mentioned, no help is given in the paragraph on the diagnosis of this disease and of the diagnosis of syphilitic laryngitis it is merely said that this is usually made by means of the Wassermann reaction. We must protest too against the statement that the routine method of combating dysphagia in tuberculous laryngitis is the free use of cocaine.

The best part of the book is that which deals with diseases of the ear where the description of acute otitis and its complications is particularly lucid. When discussing the use of drugs accurate doses and concentrations might usefully have been given. Boric and iodine powder is recommended for aural suppuration but the proportions of the mixture are not stated in the text or in the appendix. Carbolic acid at a strength of 4 per cent. is advised in the acute stage of otitis media but whether in aqueous solution with a syringe or as drops is not mentioned. In the short appendix on formulae ear drops of carbolic acid in glycerine are given at a strength of 6 grains to 2 ounces, or about one half per cent., an unusually weak solution and under Biegvad's drops the proportion of cocaine is not stated. We point out these errors of detail because they are important in a book intended for use in a doctor's practice and because we hope that they will be corrected in a subsequent edition. On the whole the teaching is clear and definite and the advice given is so sound that the work should have an established place among the smaller text books on its subject.

Biological Laboratory Technique

By J BRONTE GATENBY B.A. B.Sc. D.Phil. Oxon M.A. Ph.D. Dublin D.Sc. Lond. Professor of Zoology and Comparative Anatomy Trinity College Dublin University London J and A Churchill 1937 Pp 130 7s 6d

Owing presumably to the variability of the materials used there is no such thing as a standard result obtained when making a microscopical preparation of a given tissue with a given procedure and reagent. The worker must get to know his materials

by experience and he obtains his results by a process which he can demonstrate but can rarely explain. If microscopy is like cooking an art most books on microscopical technique have the same limitations of function as do books on cookery. Prof Gatenby's work however should be valuable to teachers and to those who are beginning research mainly because he gives hints on just those minor but important points of detail which are generally omitted from text books. An original and particularly useful chapter is the one dealing with methods of observing the structure and behaviour of the living cell, for the sight of a living cell is a lamentably rare experience for the average student of histology. The section which provides an introduction to the technique of microchemical testing will also be welcomed.

The title of the book is somewhat misleading since it deals solely with microscopy.

Recent Advances in Orthopaedic Surgery

By B H BURNS B.A. B.Ch. FRCS Orthopaedic Surgeon to St George's Hospital and J H ELLIS M.A. B.Ch. FRCS Orthopaedic Surgeon to St Mary's Hospital London J and A Churchill 1937 Pp 206 15s

The authors of this excellent little book emphatically state that it is not intended to be a text book but only a discussion of views held to day on certain orthopaedic subjects. Nevertheless they survey a very wide field and contrive to compress into a small space an enormous amount of valuable information. They achieve this by a rigid economy in words without sacrificing clearness by careful choice from a laborious study of the literature and by the avoidance of unnecessary detail. They have interpreted advances in its widest sense—implying not only additions to knowledge but also the standardisation of ideas and methods previously in use. The acceptance for instance of Alhson and Gormley's classification of arthritis does not bring new knowledge but does certainly introduce order out of chaos. Some knowledge on the part of the reader is assumed but the appeal is not only to orthopaedic surgeons.

Subjects of interest to general surgeons and to students such as chemistry of bone, bone tumours, acute and chronic osteomyelitis, tuberculous joints and coxa vara to mention only a few are included and at the end of each chapter a carefully chosen bibliography of the more important works are appended. When an article, book or discussion at a medical meeting has seemed to be particularly significant it is summarised and made the subject of a complete chapter. It will be generally agreed that the article on that obscure subject—the painful shoulder—is particularly valuable. Few students will have the time or inclination to read Codman's admirable work and the authors have rendered a service in summarising it so excellently.

The writing of a book on recent advances is an opportunity of reviving good ideas that run the risk of being forgotten and it is surprising that no reference is made to Kindsa's work in connexion with the importance of correcting the anteversion of the neck of the femur in the treatment of congenital dislocation of the hip. The omission is the more surprising since in the X-ray which is reproduced to show a result of a shelf operation the head of the femur is anteverted by about 70 degrees. Apart

from this everything seems to have been included which can be interpreted as an advance during the last five years, and placed in its proper perspective. The book is small and easy to handle, and contains ample and well chosen X rays and diagrams. It fills a long felt gap, and should find its place on the bookshelves of surgeons interested in bone and joint disease. It is a book that will be easy to keep up to date, so that it should become a standard work for those studying for higher qualifications.

Fundamentals of Human Physiology

Fourth edition. By the late J J R MACLEOD, M.B., D.Sc., F.R.S., late Regius Professor of Physiology in the University of Aberdeen, and R J SEYMOUR, M.S., M.D., Professor of Physiology, Ohio State University, Columbus, Ohio. London: Henry Kimpton, 1936. Pp 424. 10s 6d.

To revise even a small book which is twelve years old is a heavy task. Prof Seymour has done it well, this work remains a reliable exposition of the fundamentals of human physiology, and as befits an introductory text book, includes adequate information on anatomical and chemical points. It leaves no part of the subject untouched, having chapters not only on the special senses, but on subjects such as immunity, nutrition, and hygiene. Physiology is therefore presented in perspective, an important feature for the student who wishes to understand its scope and main principles without reading too widely. The editor states that the section on metabolism has been cut down by half and that on the endocrines expanded, but nutrition, digestion, and metabolism still cover a hundred pages, while the ductless glands are given only fifteen. The balance of the book thus needs attention in this direction if it is to represent modern physiology in miniature. It may be conceded, however, that the present arrangement accords sufficiently with the title, and in a work of this size sins of omissions must not be treated too seriously.

British Journal of Surgery

THE April issue contains the following papers —

CARCINOMA OF THE MALE URETHRA with report of a case. By Henry Mortensen (Melbourne). The rarity of the condition is noted and its association with persistent stricture requiring repeated dilatation. Suspicion should be roused when dilatation is unsatisfactory and there is a persistent discharge of blood from the urethra. Squamous metaplasia of the epithelium occurred in the case reported.

FAT EMBOLISM report of a case, with review of the literature. By A J Watson (London). A fatal case is recounted. The origin of the fat emboli—either from the medullary fat or by aggregation of the fat emulsion of the plasma—is discussed. The symptoms may be pulmonary, with fat in the sputum, or systemic, with delirium, and fat in the urine.

PYELOGRAPHY IN RENAL HYDATIDS. By R Campbell Begg (Wellington, N.Z.). The characteristic deformity of the pyelogram can decide the side, nature and site of the lesion. In the absence of hydatids in the urine it differentiates hydatid disease of the liver, spleen, or perirenal region from that of the kidney.

MULTIPLE VILLOUS PAPILLOMATA OF THE GALL-BLADDER. By F R Brown and D F Cappell (Dundee and St Andrews). Cholecystectomy was performed for acute cholecystitis, and multiple calculi were found.

A CASE OF RUPTURED ANEURYSM OF THE SPLENIC ARTERY WITH RECURRENCE. By Clifford G Parsons (Birmingham). Rupture occurs first into the lesser sac, and only secondarily into the general peritoneal sac. Operation stands more chance of success in the first

stage. In the case described ligation of the artery and splenectomy were followed by recovery. The recurrence was fatal, owing to technical difficulties of the operation.

ONE STAGE LOBECTOMY FOR HYDATID DISEASE OF THE LUNG. By A L d'Abreu (Cardiff). The cyst was subpleural and probably on the point of rupture into the pleural cavity. There had been symptoms for 42 years. The patient, aged 60, made a splendid recovery with primary healing of the wound.

EFFECT OF BRACHIAL PLEXUS BLOCK ON PATIENTS SUFFERING FROM SECONDARY TRAUMATIC SHOCK. By H J B Atkins (London). It was hoped to protect patients with severe injuries of the upper limb from the nervous impulses causing secondary shock. The result of the block was a large fall of blood pressure. This is attributed to the general action of the local anæsthetic, independent of the site of injection.

FIXATION OF THE HIP JOINT BY MEANS OF AN EXTRA ARTICULAR BONE GRAFT late results. By Hugh C Trumble (Melbourne). A strong tibial graft is implanted between the ischial tuberosity and the upper end of the femoral shaft. The results in 8 cases of tuberculosis of the hip are encouraging. The tuberculous process has healed or is quiescent, and many of the patients have returned to their original occupations.

TREATMENT OF FRACTURED PATELLA BY EXCISION a study of morphology and function. By R Brooke (Chichester). The author thinks the patella has no useful function. Experiment on the cadaver shows that extension is more effective in its absence, and in 30 cases of fractured patella removal has been followed by rapid recovery of full function.

A NOTE ON THE EXTENSION APPARATUS OF THE KNEE JOINT. By W Hey Groves (Bristol). The insertion of the quadriceps tendon is shown to occur almost independently of the patella. The importance, in operations of repair, of preserving and suturing the lateral expansions of the quadriceps is noted.

SOME REFLECTIONS ON GASTROSTOMY. By E S J King (Melbourne). Experience of 60 cases has led King to set down principles that should guide the surgeon in the choice of operation and in subsequent feeding. Attention is drawn to the advantages of solid food.

EXPERIMENTAL LESIONS OF THE RABBIT'S APPENDIX. By A Q Wells (London). Gangrenous appendicitis followed ligation of the appendicular vessels and the meso-appendix. Obstruction of the lumen of the appendix, associated with a lesion of the mucosa, caused appendicitis and death. Obstruction of the lumen alone caused mucocele. Ligation of the root of the appendix and of the vessels caused atrophy of the appendix, without inflammation.

INTESTINAL STRANGULATION. THE HISTAMINE CONTENT OF THE PERITONEAL EXUDATE FROM STRANGULATED INTESTINAL LOOPS. By Ian Aird and W K Henderson (Edinburgh). An 8 inch loop of lower ileum was isolated in a rubber bag. The histamine content was tested by the effect of extracts on blood pressure of atropinized cat, on rat uterus, and on virgin uterus and ileum of guinea pigs. The total content amounted to as much as 4 mg. Although this amount is large, histamine is not to be regarded as the sole lethal factor in the exudate. Its bacterial origin is not wholly accepted.

EXPERIMENTAL OBSERVATIONS ON THE SPREAD OF CARCINOMA BY THE BLOOD STREAM, with special reference to the difference between the portal and systemic routes. By David H Patey (London). A dilute emulsion in saline was used of the Brown Pearce tumour of the scrotum of rabbits. Injection into the portal system of rabbits in 41 cases was followed by visceral tumours in 7. Similar injection into a systemic vein gave visceral tumours in 30 out of 44 cases.

BASIS OF TREATMENT OF VASOSPASTIC STATES OF THE EXTREMITIES an experimental analysis in monkeys. By P B Ashcroft (London). The immediate and late effects of pre and post ganglionic division of the sympathetic nerve supply to the limbs was studied by skin temperature records. Post ganglionic division was found to produce a great increase in adrenaline sensitivity and an increased sensitivity to cold. It is suggested that this may account for 'recurrences' after operations of sympathectomy on the upper limb, and that pre ganglionic section is a better operation.

THE LANCET

LONDON SATURDAY MAY 1 1937

INJURIES OF THE FACE

FEW of us reach maturity without having on some occasion suffered acute embarrassment from the consciousness of a facial lesion—be it only a scratch or mole or pimple. An assurance that others have not noticed it is offensive rather than comforting for the oriental expression which identifies face with self-esteem implies but little exaggeration of the normal attitude. More serious and permanent lesions whether congenital such as cleft lip or naevi or acquired such as tissue loss or distortion after a wound or accident, can indeed inflict such mental trauma that the development of plastic surgery to its present high level is of far more than æsthetic value. BLAIR BROWN and BYARS¹ in a recent study of injuries of the face note that a conviction of deformity may even persist despite the most perfect repair and that unless it is wisely handled may destroy the value to the patient of any operative measure. It is of the utmost importance then to avoid procedures immediately after any injury which will increase the final scarring. Often the plastic surgeon is more embarrassed by the scars of primary sutures or by the results of immediate débridement than he is by the direct effects of the injury. On the other hand in fractures of the face delay may be even more dangerous from the cosmetic point of view than immediate repair by one who is not an expert since according to these authors once solidification occurs satisfactory reposition of bones of the face is nearly always impossible. In their article on prognosis in plastic surgery GILLIES and MOWLEM² take a different view holding that where there is no skin lesion demanding immediate treatment accurate reposition of the bony fragments may be facilitated by waiting for a week or so to allow swelling to subside. The position of the fragments can then be more readily ascertained by palpation and their replacement more exactly controlled. It must be remembered however that the procedure must depend on the degree of specialised experience of the surgeon and that the American authors are addressing the general rather than the expert plastic surgeon.

In treatment of injuries of the soft parts the first rule is not to sacrifice tissue. A great deal of faith can be placed in the vitality of flaps of facial tissue. In certain types of injury to the soft parts primary suture is also important. Blair Brown and Byars cite four in particular. In the trap-door flap with a narrowly bevelled edge delay in suturing the thin edge into position may

lead to its crumpling up in the scar with an obvious cushioning of the tissue beyond it. Careful reposition of torn pieces of ear again may be the only chance of preventing distortion. Narrow double-surfaced flaps as at the border of the lip ear or eyelid if left hanging are apt to become so twisted as to be unusable in a subsequent repair. Finally it is recommended that all cuts and tears of the skin of the nose and its cartilage be immediately closed with sutures as this may be extremely difficult to do later on. In this connexion we may note that in a recent publication another American surgeon J. EASTMAN SHEEHAN³ deals with the repair of cartilaginous defects of the nose in very great and useful detail, though his views on the utilisation of cartilage in preference to bone for the restoration of major losses of the bridge line do not correspond with modern British practice. In the nose immediate reduction of bony and cartilaginous displacements of the parts is advisable for a late replacement may be a formidable procedure. There is a difference of opinion among experts as to the value of intranasal packing in retaining the reduced fragments. Blair Brown and Byars use a metal splint in cases which do not remain reduced without difficulty. They draw attention to the importance of nasal injury in small children. The possibility of distorted growth of the septal cartilage resulting in later life should be remembered even after injuries that at the time seem trivial. Their practice is to explain the position to the parents and obtain consent to make forcible pressure on the bony ridge from within so as to straighten any bend in the septum.

The value of co-operation with the dental surgeon in all fractures of the jaws is well recognised in this country. Often the repair is primarily an orthodontic problem. The two methods now employed are interdental wiring and the dental splint. Almost any fracture with sufficient displacement to require splintage must be compound. Ordinary wire buried in the jaw will in most cases result in osteomyelitis and bone loss. Possibly the passage of wire through the alveolus of the fragment with fixation to an adjacent tooth is a safer method since the wire can be recovered in a week or two. The involvement of the tooth socket in a fracture of the jaw is a complication which needs attention. If necessary drainage must be provided by an external incision under the border of the bone right up to the slit that enters the socket. The edentulous jaw presents its own problems but they can often be met satisfactorily by use of the dental plate or plates. But if the case is seen early such heroic measures are seldom required. It is essential to remove any teeth which lie either in or very near to the fracture line since they will act as foreign bodies, the open sockets thus created usually supply sufficient drainage. The importance of avoiding thorough suturing of the skin with thick sutures of silk or silkworm gut should be impressed on all casualty officers. When horse hair sutures removed in 48 hours or so are obviously insufficient

¹ Blair B. Brown, J. B. and Byars, L. T. (1935) *Surgery, Gynec. Obstet.* 64, 35A.
² Gillies, H. and Mowlem, R. (1936) *Lancet* 2, 1111.

³ Plastic Surgery of the Nose, 2nd edition, by J. Eastman Sheehan. London: H. K. Mulholland, 1936. 246 pp. 17s. 6d.

to retain the tissues in accurate apposition, much can be done with subcuticular stitching which is nowhere more valuable than on the face. Subdermal interrupted sutures of very fine silk may be inserted in deep wounds if the ends of the suture are left protruding from the corner of the wound to allow of the knot being subsequently discarded. Adhesive plaster is often better than any suture, and injuries of the lips can sometimes be repaired from the mucous surface with adhesive plaster to hold the skin edges. It is sometimes unwise to bury catgut in the lip and the repair may be effected by fine silk or silkworm gut for skin and fine catgut for muscle and mucous membrane.

HYPERTONIC SUCROSE

INTRAVENOUS injections of a hypertonic solution of dextrose—or sodium chloride—are commonly employed in the treatment of states of raised intracranial pressure. The fall in the intracranial pressure which results from such an injection has been measured in experiments upon animals and by direct manometric observations in humans, the reduction of pressure has been found to be more conspicuous when the pressure is considerably above normal. This form of treatment is not always successful in effecting clinical improvement, and it is well recognised that after a short interval of time a relapse is liable to occur which may leave the patient in a more serious state. There is experimental proof that such relapses are due to a reactionary rise of the intracranial pressure at times to a figure above its former value. This reactionary rise indeed constitutes a serious drawback to the method of treatment, although repeated injections may be given to obviate it. If sucrose is substituted for dextrose, hypertonic solutions are found to possess a similar osmotic property of reducing the intracranial pressure, but without the objectionable reaction. Following the intravenous injection of hypertonic dextrose, there occurs an increase in the quantity of hydrolysable carbohydrate in the cerebrospinal fluid which is not observed if sucrose is employed. It is likely that the mechanism of the reactionary rise in the intracranial pressure depends on this alteration in the composition of the cerebrospinal fluid and consequently of its osmotic pressure. HAHN, RAMSEY, and KOHLSTAEDT¹ have recently published a short review of this subject of "osmotic therapy," with special reference to the treatment of cases of brain injury. In a series of twenty-five such patients, they gave single or repeated doses of sucrose, usually 100 c cm of 50 per cent solution. Their experience leads them to consider sucrose a valuable substitute for dextrose, causing an effective reduction in the intracranial pressure with freedom from untoward after effects. They record in detail the notes of three cases treated in this manner. The injections noticeably improved the patients' colour, respiratory rhythm, and state of consciousness, and reduced the systolic and diastolic blood pressures.

The authors consider that criteria such as these are as dependable as the unequivocal information obtained by spinal manometry. They note that in the unconscious patient, the too frequent injection of hypertonic solutions may lead to dangerous dehydration, owing to the resulting diuresis. We would add that intravenous therapy should not be resorted to indiscriminately in cases of injury to the brain, some of these cases have an abnormally low intracranial pressure, a state which might be aggravated by this form of treatment.

THE SHORTAGE OF VETERINARY SURGEONS

IN the April issue of the *Veterinary Journal* a special educational number, there are points of great interest not only to boys seeking a career and their parents or advisers, but to all practitioners of medicine, from their position as guardians of the public health. Here the two branches of medicine, the human and the veterinary, play individual and combined parts, and any shortage in the total number of the veterinary body may reflect seriously upon the joint efforts. For the diseases of animals which are communicable to man are far spread in their evil influences. In this country anthrax, glanders, and rabies are now fortunately rare if terrifying spectres. Their eradication is mainly due to the control exercised by the veterinary department of the Ministry of Agriculture and Fisheries over their respective sources of origin, bovine, equine, and canine. It is to be hoped that we shall never again in this country have to fear these terrible menaces to man, but this security depends upon the continuance of the present keen veterinary inspection at each port where animals are allowed to land, as well as on quarantine laws and those governing the importation of animal products. Efforts directed towards prevention of the spread to humans of brucella infections and of foot and mouth disease must also be recalled. In the inspection of meat for human food the man who must by virtue of his training know most about the matter is the veterinary surgeon. He is the one best qualified to detect disease in the food animal before slaughter and to guarantee the soundness of the flesh when dressed for human consumption. And in the present fight against tuberculosis, which is an uppermost theme in every mind, the medical man works with the veterinarian, and only through such collaboration can measures of prevention be considered or a successful conclusion to endeavour be anticipated.

The editor of the *Veterinary Journal* draws attention to the shortage of veterinary surgeons throughout the country and the difficulties which exist in obtaining the help of qualified assistants. This is to be attributed largely to the openings existing in the Colonies, and the recently formed Veterinary State Service, whose most urgent duty—the eradication of the tuberculous cow—absorbs many workers. It is necessary to bear constantly in mind the fact that every year between 2500 and 3000 deaths of children under 5 years of age are traceable to the drinking of tubercle infected milk.

¹ Hahn F, Vernon Ramsey, Frank B, and Kohlstaedt Kenneth G (1937) *J. Amer. med. Ass.* 108 713

If reliance is placed upon many published statements there are some million tuberculous cows in Great Britain and Ireland while in many districts the dairy herds are infected to the extent of from 30 to even 60 per cent. As recently as last Tuesday Lord Dawson reminded the House of Lords in connexion with the present need for pasteurisation of milk that the decline in mortality from bovine tuberculosis had not kept pace with that from the human form of infection. If an intensified effort to eradicate the tuberculous cow is a great task before the veterinarian we are reminded how varied and important are the other directions in which his services are required in the promotion and protection of public health. The shortage of qualified veterinary surgeons is therefore a matter of real concern. The young man entering the

veterinary profession to-day will find that he has joined a service which is increasingly needed and valued the whole world counts on his help. But the more this is so the more evident is it that the educational course must become increasingly comprehensive and the tests to be satisfied grow harder. An extension of the curriculum has already been made and university courses are running concurrently with those connected with the practising diploma but the danger of discouraging candidates by insisting on too prolonged and arduous a course of study must be borne in mind. Students entering the veterinary profession now will command better material rewards than has been possible in the past as there are almost limitless possibilities of promoting the welfare of the human as well as the animal kingdom.

ANNOTATIONS

RADIOTHERAPEUTIC HOSPITAL DEPARTMENTS

THE assumption which pervades the official memorandum on provision of radiotherapeutic departments in general hospitals just issued¹ is that any discussion in general terms as to the place of surgery, X-ray and radium therapy in the treatment of cancer is obsolete. In about 40 per cent. of the cases of malignant disease admitted annually to hospitals the tumours are in the so-called accessible organs, the term accessible being used to define those which are most amenable to treatment by radiation or a combination of it with surgery—viz. uterus, mouth, skin and breast. Radiation methods are also being tried with varying degrees of frequency and success for a proportion (here estimated as about 10 per cent.) of the patients with cancer in other regions. Since much can be done in the way of palliation by radiation methods no sharp distinction can be drawn between cases treated with or without hope of permanent benefit. The need for facilities for treatment by both forms of radiation methods—radium and X-rays—as well as for operative surgery in a general hospital which claims to give an adequate cancer service is now recognised and the problem is narrowed to the calculation of the size of hospital which may be expected to yield enough cancer patients to make reasonably full use of radiation facilities. Lieut. Colonel Smallman who has compiled this memorandum for the Ministry of Health estimates this at a hospital of the order of 300 beds of which some 30 to 40 might be expected to be required by cancer patients of the treatable types. The necessary provision of radium for a hospital of this size is put at about 1.0 gramme of radium and for deep X-ray therapy two or three tubes working at a voltage of 200–250 kilo volts and two model layouts for a department of this order are detailed with plans. Provision of larger masses of radium for distance therapy by so-called bombs is omitted from consideration as being in a stage of development which makes it suited only to the larger centres. But attention is given to the choice, training and organisation of a unit which will provide the necessary team work in the absence of a director—still very difficult to find—who is expert at all three branches of treatment and is able also to supervise the follow up

department and the collecting of records in suitable form. Apart from the internal organisation of centres, which will make an efficient cancer service available throughout the country arrangements must be made for cases of cancer admitted to the smaller hospitals to be transferred to those with radiation facilities without undue delay when such transference seems desirable. The difficulties to be surmounted before this sort of scheme can be got into working order are fully recognised by Colonel Smallman and a study of his discussion of the issues involved will convince those who have the responsibility for hospital services that there is no excuse for delay in organising a network of fully equipped centres to serve those districts which still need them. In a preparatory note Sir Arthur MacNalty acknowledges the courtesy of a number of physicians and surgeons who have made useful suggestions after considering the memorandum which he believes to represent a consensus of authoritative medical opinion on the subject of radiotherapeutic hospital departments.

THE ROYAL SURGICAL AID SOCIETY

THE Royal Surgical Aid Society in the course of 75 years' activity has provided well over a million patients with urgently needed surgical appliances. It has since the opening of the century received Royal patronage and the occasion of the Coronation is being taken to make a departure which should lead to an extension of its valuable services. The plan of work is that the patient obtains a certificate from a surgeon of fitness for aid and then collects from subscribers to the Society the number of letters of recommendation specified as necessary. An initial subscription of half a guinea or a life subscription of five guineas entitles the subscriber to two recommendations per annum the number of recommendations increasing in proportion to the amount of subscription or donation. That is the present method but in order to mark the extent of the celebration the committee of the Society propose to double the usual number of recommendations in respect of all special Coronation donations during the month of May. The increase will be for those whom the Society can help by the gift of a loan which will mean a boon to many suffering from lack of funds for aid are always for the most part dealt with. Study of the figures for the year 1936 reveals something of the extent of the work of the Society's work. During the year 1936 the

¹ Cancer Memorandum on Provision of Radiotherapeutic Department in General Hospital. By A. H. Smallman (R.L.S. D.304. 31.1). Rep. Med. Adm. Serv. Conf. No. 79. London: H.M. Stationery Office, 1937. Pp. 3. 7d.

obtained help through the Society, and the appliances supplied totalled 35,263. Requests received from the distressed areas were so numerous that a special fund was created to deal with them, and a successful appeal was launched enabling special grants to be made to all authorised distressed area cases.

A valuable aspect of the work of the Royal Surgical Aid Society is that, while relieving much distress, it enables the benefactors who would otherwise be chronically handicapped to lead normal and useful lives. The annals of the Society are full of such promising histories, and every day applications are received where similar fortunate issues might be anticipated. In the L.C.C. housing estates preference is being given to tenants having delicate families, who thus form fields where surgical equipment is sadly needed. The Surgical Aid Society hopes in the Coronation year to receive support enabling it to help every suitable case from these areas.

THE BLOOD GROUPS IN AFFILIATION CASES

THE discovery of four, and later of twelve blood groups provided means of differentiating to some degree between the blood of different persons. Ever since it was discovered that the group characters are inherited according to unvarying rules, jurists have considered using this knowledge in the determination of affiliation suits. In most civilised countries the law requires the father of an illegitimate child by a single woman to contribute to its maintenance. Accusations of paternity are difficult to prove and the law of this country is satisfied with credible evidence by the mother corroborated in some material particular, provided that the evidence of the man does not refute it. A method of reaching greater certainty is therefore desirable.

The Medico Legal Society discussed on April 22nd, under the chairmanship of its president, Mr Ainsworth Mitchell, the practical and legal possibilities of using blood groups in evidence. Dr G. Roche Lynch explained the nature of the twelve groups formed by combinations of the agglutinogens A, B, M, and N. He explained that almost all the original weaknesses of the laboratory methods have been recognised and abolished and that in experienced hands the tests are as nearly infallible as any scientific tests can be. Dr David Harley expounded the rules by which the blood characters are inherited, and maintained that they are so completely authenticated as to be absolutely trustworthy. They state, shortly, that a child cannot inherit a blood character not possessed by either parent, and, moreover, that an O child cannot have an AB parent and vice versa. Mr D. H. Kitchin pointed out some of the difficulties in the way of the legal exponents of the tests. Their cost, he said, puts them beyond the means of the poor men who are usually the defendants in affiliation proceedings. He had little doubt about the need for them, and strongly opposed the view, which is held even in some legal quarters, that the law only requires reasonable proof that intercourse has taken place at the proper time, and not proof of biological paternity. It is common knowledge that women of easy virtue who find themselves pregnant not infrequently choose the man who is most likely to be able to afford the maintenance of their child. At present, as Mr Kitchin pointed out, a bench of magistrates has no power to order the woman to undergo the test nor even to refuse her application because she will not. If all three bloods are typed and the results acquit a man, he still has to pay a considerable fee to the pathologist to come and give evidence.

It is not possible yet to say what the attitude of magistrates is likely to be towards blood group evidence, for it has only been brought before them once or twice and then has never pointed to an acquittal. There is no doubt, as Mr Kitchin said, that the first case in this country in which non-paternity is definitely established will be very interesting and important. If the bench were to refuse to acquit the man in appeal would he to quarter sessions and thence to the Divisional Court, and an opportunity would be given for a full argument of the validity of the tests in a court. Their establishment in one or two conclusive cases would pave the way for the legislation which would be necessary before they could attain their rightful place in the administration of the Bastardy Acts. It would be necessary to place some compulsion on the mother, as Judge Earengay, K.C., put it, the bench should have power, if the mother refused her co-operation, to grant an indefinite stay of the proceedings. It would also be necessary to provide that, unless one of the parties particularly desired the oral evidence of the pathologist, his certificate should be conclusive proof of the result of the test. Further, it would be necessary, to get the full value from the tests, to give the magistrates power to have them done at the public expense.

The most important feature of the discussion was the strong support of the movement by Sir Travers Humphreys, whose position and reputation as a judge of the King's Bench Division give his opinion authority. He said that the whole legal profession would welcome the blood group tests if they were shown to further the cause of justice. He saw no real difficulty in saying in an Act of Parliament that a woman shall, if the court so direct, submit to a simple, painless operation. He also considered that the bench should have power to appoint an expert to do the test, just as a High Court judge is now allowed, under the New Procedure, to appoint an expert to report on any matter of scientific difficulty. Both he and Sir Ernest Graham Little considered that the future of the blood group tests in law depended very largely on the agreement of the medical profession that they are trustworthy.

THE PROMOTION OF LACTATION

THE influence of various hormones upon lactation is being studied closely at the present time from several aspects, of which that represented by agriculture is of great economic and commercial importance. S. J. Polley at the National Institute for Research in Dairying, Reading, has shown in conjunction with F. G. Young¹ that prolactin, one of the many hormones derived from the anterior lobe of the pituitary, can greatly increase the production of milk. Two dairy shorthorned cows in declining lactation were used for the experiment. One received 15 daily subcutaneous injections of 1 gramme of prolactin in 50 c.c.m. of water, the other was given similar injections of distilled water. The cow receiving prolactin developed an increase in milk yield, rising to a maximum of 30 per cent above the original daily yield. The percentage of fat in the milk remained unchanged while the injections were being given, while the percentage of non-fatty solids in the milk was considerably increased during this period and for some time afterwards. Polley has also studied the effect of oestrogenic hormones on lactation.² Four Guernsey cows were given injections of oestron, partly in solution and partly suspended

¹ *Chem. Ind. Rev.* 1937, 56, 86.

² *Biochem. J.* 1936, 30, 2262.

in warmed castor oil, supplemented by a small amount of a solution of dihydrofollicular hormone benzoate in sesame oil (the Progyron B Oleum forte prepared by Messrs Schering). The injections were intramuscular and preceded by a control period of at least 14 days and the following calculations were made for successive three-day periods: mean daily milk yield, mean daily production of milk fat, mean daily production of milk non fatty solids, mean percentage of fat in milk and mean percentage of non fatty solids in milk. The results showed that oestrogenic hormone injections were always followed by a considerable diminution in milk yield. The inhibition was temporary and was obviously correlated with a transient but considerable increase in the level of oestrogenic hormone in the blood. An attempt was made by giving to one cow simultaneous injections of the oestrogenic hormone and prolactin to determine whether the inhibition is exerted primarily on the anterior pituitary or whether it is a direct effect on the mammary gland; unfortunately the results were inconclusive. The effects of the oestrogenic hormone on the composition of the milk were remarkable suggesting that the treatment had conferred upon the mammary gland the power to synthesise milk constituents at a higher rate than before treatment. An increase in concentration of solids in the milk secreted lasted for two or three months. These investigations have an obvious interest for those concerned with promoting the breast feeding of infants though the direct application of the results of such studies to the human subject would not be easy especially in view of the superstitions which have accumulated round the subject of breast feeding. P. J. Greenway,* who is the systematic botanist at the East African Agricultural Research Station in Tanganyika Territory has recently recorded some interesting observations on the artificial induction of lactation in women by administration of various concoctions both by mouth and by local injection. He records over a dozen plants which have a reputation in the territory as galactagogues and there seems little doubt that some activity in the breast even of women who would not otherwise be lactating can be induced by their use. Greenway suggests that the plants he mentions may have some action on the hormones which control lactation.

THE EFFECT OF VENOUS STASIS ON BONE REPAIR

THE acceleration of bone growth in conditions of venous stasis, clinical as well as experimental is discussed by Herman L. Pearse and John J. Morton† in the first issue of a new American journal which we have already had occasion to notice‡. The association between chronic cardiac and pulmonary disease and bone changes in the fingers—the well known club fingers—has long been recognised and Pearse and Morton mention various local circulatory changes associated with haemangioectasis, arteriovenous aneurysm and meningioma which have been held responsible for overgrowth of bone. They have conducted experiments on dogs by which they claim to have demonstrated a direct acceleration of bone repair in artificially produced defects in the fibula by ligation of the popliteal vein. These experiments were first described in 1930 but since they were challenged by J. A. Key and F. Walton further

work has been undertaken. Pearse and Morton have now done 28 experiments on dogs fibulae and those have shown an increase in the rate of healing in 25 on the side with venous congestion. The progress of repair is controlled by X-ray examination. Great care is necessary to maintain the continuity of the periosteum as failures in bony union occur if muscle is allowed to interpose between the fragments. Bleeding is avoided by approaching the fibula through the plane of the intermuscular septa and care is needed to distinguish the popliteal vein which it is intended to ligature from the lesser saphenous vein. The requirements laid down by Pearse and Morton for these experiments are that post operative splinting shall be avoided, that functional disability shall be minimised, and that damage to the circulation shall be absent. Failure to reproduce their results are attributable in their opinion to some imperfection of technique. They have found however that repair of bone in young animals is so rapid that it is difficult to accelerate it further and this also may account for certain anomalies. The object of this study was to explain the clinical results reported by other observers and to suggest that venous stasis has a place in the treatment of fractures in the human subject.

THE CHEMOTHERAPY OF STREPTOCOCCAL INFECTIONS

A FLOW of literature dealing with the therapeutic use of Protosil and sulphonamide is now in full current. What is more particularly needed at the present stage is guidance on such matters as dosage, the type of preparation to be used and the effect to be expected in different types of infection by *Streptococcus pyogenes*. A solid contribution on these lines is made by Long and Bliss† of the Johns Hopkins Hospital, Baltimore who have treated 10 cases of such infection involving various parts of the body. Among these there were 4 deaths, two being cases of Ludwig's angina, one a septicæmia in extremis and the fourth an infant with peritonitis. The recoveries included 22 cases of erysipelas and cellulitis, 27 of acute infections of the upper air passages including 8 of scarlet fever, 9 cases of otitis media and smaller numbers of septicaemia, purpural fever and other miscellaneous conditions. Long and Bliss are convinced of the efficacy of the treatment. They have used both protosil injections and oral sulphonamide; their dosage is heavy (up to 5 grammes of the latter daily), and they report few signs of toxic action including only three examples of sulphuric globulinæmia. That an adequate concentration of the drug can be maintained continuously in the blood and tissues by present methods of administration is indicated by the useful work of Marshall Emerson and Cutting‡ who have studied the absorption in vivo distribution and excretion of sulphonamide given either by injection or by the mouth. This is a straightforward pharmacological study of a kind which is apt to find a too isolated place when enthusiasm for a new remedy outstrips the orderly progress of its study. The investigations which were carried out in dogs show that whether the drug is given by the mouth by subcutaneous injection or intravenously a high concentration is maintained in the blood for six hours and diminishes only slowly owing to the very gradual rate of elimination in the urine. It was likewise shown that a concentration in

J. Amer. med. Ass. 108, 933.

equivalent to about half that existing in the blood is attained in the cerebro spinal fluid, a fact of great importance in relation to the possible treatment of streptococcal or meningococcal meningitis.

Another aspect of research on these drugs is concerned with their effect on bacteria other than streptococci. It will be recalled that Dr G. A. H. Buttle and his colleagues recently reported in this journal² experiments from which it appears that sulphonamide has a remarkable action, in mice, on infection by typhoid and paratyphoid bacilli, and lesser degrees of effect in infection by a number of other bacteria. Among these was the pneumococcus, and the findings in connexion with this organism were distinctly less encouraging than those reported by Rosenthal.⁴ There is a discrepancy here which has yet to be explained, and for the time being a proper inclination would be rather to accept the results of the more experienced workers in this field. On the whole it seems advisable for the present not to build serious hopes on these wider explorations: there is no shorter road to discredit of any drug than its indiscriminate use. Sulphonamide cannot be expected to do everything, and the detailed knowledge of antiseptic action which has been accumulating for years all points to a curious specificity among the most active agents we possess, some bacteria being highly susceptible and others comparatively resistant. Now that effective chemotherapy is shown to be possible in at least one bacterial infection, it may be that altogether other chemical weapons will be forged with which to combat others.

INSTITUTE OF CHILD PSYCHOLOGY

Too much stress is sometimes laid, in psychological work with children, on the prevention and treatment of neurosis—i.e., on pathology rather than on normality. The Institute of Child Psychology believes in an approach based upon an intimate knowledge of all aspects of childhood, a direct study of the children themselves. Its staff have worked out some interesting methods peculiar to the Institute for treating children suffering from all kinds of disturbances of their emotional life, from chronic physical disorders, from maladjustment at home or at school, and from educational difficulties. One of their most successful methods is play therapy. They are concerned to make their methods available for other centres and to standardise them for general use. The report for the past year says that great progress has been made in classifying and consolidating these methods and there is evidence that much interest is being aroused in them. The staff also accumulate the knowledge they acquire about the reaction of children to life. In May the first number of the Institute's News Bulletin appeared, and the bulletin is now self supporting at a nominal annual subscription. Two group discussion meetings were held and courses of public lectures were well attended. During the autumn members attended a course of lectures by Prof. R. G. Collingwood on the study of fairy tales. The Institute sends its play therapists to a special clinic at the West End Hospital where children are treated for night terrors, anxiety, speech difficulties and other disorders of health and conduct. A special department treats children individually instead of in groups and provides useful training for physicians who wish to learn the psychotherapy of childhood. Children are examined for physical ailments in a medical department and an effort is made

to give them the treatment they need. The educational department collects and coördinates school reports, arranges special coaching and studies the relationship between emotional inhibition and freedom to use the intelligence. The social worker dealt last year with 130 cases, including the heavy work of after care, and of finding suitable help for children who could not be treated at the Institute. Another department cares for the physical re-education of children by rhythmic exercise. Parents are welcomed at the institute, which recognises their importance in the child's problems and encourages them to deal with their own. A generous donor has promised to buy the Institute a larger house as soon as it can find a suitable building.

THE PHOSPHATASES

THE phosphatases are assuming a steadily increasing significance in several departments of physiological and medical research and papers on the subject are multiplying rapidly. As usual these find their way into a wide variety of journals, not all of which are readily accessible to medical workers. Mr S. J. Folley, Ph.D., and Prof. H. D. Kay¹ of the National Institute for Research in Dairying, Reading, have performed a useful service by summarising in tabular form what is known about the properties of the various phosphatases, their distribution in mammalian tissues and fluids, and the changes which they exhibit in natural or experimental disease. They have compressed a great deal of information into a surprisingly small space and their review should be very helpful to anyone who is seriously interested in these enzymes.

JOHN BLAND-SUTTON

As a supplement to the *Journal of Obstetrics and Gynaecology of the British Empire* for the April issue there is published a biographical essay on John Bland Sutton written by his colleague and close friend, Sir Comyns Berkeley. The story, admirably told, wanted telling in detail, because Bland-Sutton's career—his successes and set backs, his friendships and animosities—was sometimes puzzling even to his friends. This record, a full and moving one, while setting out in a coherent manner its subject's personality, gives interesting pictures of professional and hospital organisation at the different epochs. Cooke's popular private school of anatomy was flourishing in the 'seventies, and Bland Sutton attended it and was invited to be the demonstrator. But he refused the post, tempting to an impecunious student, and offered himself, with 100 sovereigns in a bag, as a perpetual student at Middlesex Hospital. He joined as a prosecutor, for his work at Cooke's school had been thorough, and throughout all the earlier stages of his career at Middlesex he was teaching and coaching his contemporaries. This precocious position as instructor explains the simplicity and directness of his writings and public utterances—he had taught himself to give prominence only to the things that mattered, and to provide explanations that could be followed at once. He won all the prizes at the hospital for which he competed but was unable to take a house surgeon's post, because not only was it an unpaid appointment but it necessitated the disbursement of a fee. He became instead assistant curator of the hospital museum, and worked so well that he was offered more important posts of a similar kind. These he refused, concentrating

on his aspiration to the surgical staff of the hospital. This materialised and Bland-Sutton's election as assistant surgeon was noticeable for two things. First he had never been an interne and secondly he was actually the first man trained at the Middlesex Hospital to be elected to the surgical staff of the hospital, the practice hitherto having been to draw for the staff from other and larger schools.

Bland Sutton's life was epitomised in an obituary notice in these columns. The fuller chronicle will be read with pleasure for not only is the story a very interesting one, but a vivid picture is presented of the changes that have taken place in medical education and hospital organisation since Bland Sutton was a student.

THE MEDICAL ANNUAL

We always welcome the Medical Annual,¹ and it continues to deserve its welcome. It is in the main of course a set of summaries of the previous year's most important practical papers in the world's medical literature, prepared by a number of able and distinguished contributors. But it avoids with conspicuous success the dull stodginess of most volumes of abstracts. This is partly because its contributors are free to select being under no obligation of comprehensiveness and partly because they know and understand the readers for whom they write—namely those general practitioners who are still willing to learn what is new and good in medicine and eager to give the benefit of it to their patients. The result is in most of the articles an easy clear and friendly style closer to conversation than to the language of the text-book, and this with the reviewers' skill in presenting new things in their relation to what is already familiar gives the manual a character and an atmosphere of its own. It is not merely a work of reference—one can enjoy spending an evening reading straight through it. The editors have the impression that last year was a year of steady advance in many fields without spectacular achievements and they remark that the tendency continues for the clinical and the laboratory aspects of medicine no longer incompatible to become properly compounded in the doctors' mind and practice. That process is no doubt slow but it needs judgment and a sense of proportion qualities which make the Medical Annual's own contribution to it a very useful one.

THE TREATMENT OF ADDISON'S DISEASE

DESPITE great advances in our knowledge of the function of the suprarenal glands the treatment of Addison's disease remains very unsatisfactory. This is the more depressing since both the preparation of the cortical hormone and the discovery of the rôle of salt held out great promise of therapeutic application. The reasons however are not far to seek. In the first place, as Borst and Viereira² point out failure is naturally to be expected if the Addisonian syndrome has been caused by generalised tuberculosis which in itself would ultimately have proved fatal. A second difficulty to which they also allude has been the failure of manufacturers to supply cheap standardised preparations of the hormones. A third difficulty is the seemingly manifold action of the cortical hormone or hormones. This

is brought out by Grollman³ and by other investigators. The arterial blood pressure inorganic salt metabolism carbohydrate metabolism renal function absorption from the intestine,⁴ resistance to infection, hæmorrhage and toxins all seem to be implicated and no one knows at present the relative amounts of the hormone or hormones required to restore each or all of these functions to normal. Add to this the possibility of variations in the patient's own resistance or reaction and the explanation of the therapeutic failures is complete. The case described by Dr Anderson and Dr Lynam in our present issue illustrates the difficulties that attend treatment. This patient who had been rescued from almost certain death from collapse and salt deficiency in March 1936 by cortical hormone and salt, died apparently from spontaneous hypoglycæmia in October of the same year.

It is clear that once the diagnosis of Addison's disease has been made the prognosis must still be guarded. It is also clear that haphazard treatment is never likely to be permanently successful and that the best hope for these patients lies in making a full investigation of their syndrome at frequent intervals, and in varying their treatment from time to time in accordance with the findings.

THE BRITISH ASSOCIATION

NOTTINGHAM is the place and Sept 1st-8th the time of this year's meeting of the British Association. The president is Sir Edward Poulton F.R.S. and his inaugural address will deal with the history of evolutionary thought as recorded in the meetings of the association. Medical men who preside over sections are Prof F. A. F. Crew (Zoology) and Dr E. P. Poulton (Physiology). Prof. H. Hartridge, F.R.S. will give a public lecture on Illusion of colour. Among very many subjects of interest to medical men are chemistry and medicine the changing distribution of population the contribution of physiology to the health of the individual and the community tests for colour defect recent advances in genetics and cytology problems of child guidance air-conditioning high altitude flying and the relation of grass to the national food-supply. Mr H. G. Wells presides over the section of educational science and will speak on the informative content of education. Further particulars and the provisional programme may be had from the secretary at Burlington House London W.I.

The annual meeting of the British Medical Association will open at Belfast on July 16th under the presidency of Prof R. J. Johnstone F.R.C.S. The council of the Association have recommended that Dr Colin Lindsay be elected president for next year's meeting which will be held at Plymouth.

Grollman, A. (1936) *The Adrenals* London.

THE ROYAL LYS HOSPITAL.—A clinical society has been organised in connexion with this hospital. The next meeting of the society will be held on Tuesday May 4th at 8 p.m. at the hospital when Dr J. Rowland Hill will read a paper on "neuro-muscular optics," illustrated by cases. All medical practitioners will be welcome for further particulars apply to the hon. secretary J. Minton, Royal Lys Hospital, Southwark.

SPECIAL ARTICLES

ALUM-PRECIPITATED TOXOID IN
DIPHTHERIA PREVENTION

BY J C SAUNDERS, MD NUI, D.P.H.

MEDICAL OFFICER OF HEALTH CORK

THE work to which these notes relate was undertaken in order to test the possibility of immunisation by a single injection and may be regarded as a sequel to previous work (Saunders 1932) in which multiple doses of alum precipitated toxoid (A.P.T.) were used. The reactions experienced were discussed in a subsequent article (1933), and arising from the fact that in a series of 579 children four sterile abscesses had developed, it was deemed advisable to suspend the issue of this prophylactic while further laboratory investigation was carried out with a view to producing a purer A.P.T., which would be less liable to cause unpleasant reactions and (if possible) free from the liability to produce abscesses. The A.P.T. used by us up to this point was that produced in the Wellcome Research Laboratories according to the method of Glenny and Barr (1931). Personally, I was quite satisfied with the results obtained, particularly in the immunising efficiency of the product, but those in respect of reactions were not regarded as so satisfactory by the laboratories and the result was the temporary suspension of supplies.

PRESENT PROCEDURE

The period covered by this earlier work was from June, 1931, to December, 1932, and it was not until December, 1934, that further supplies of A.P.T. were received. A description of the method of preparation will appear in another communication from the Wellcome Laboratories.*

The period covered by the present work extends from that date to December, 1936, and the procedure adopted was as follows—

1 Children under 7 were not subjected to a preliminary Schick test. They received 1 c.cm. of A.P.T. on the first visit and were instructed to attend again in five weeks for test.

2 Children over 7 received, on first visit, concurrent Schick and Moloney tests. The dilution of toxoid used for the Moloney test was 1 in 100 and readings were made in three to four days afterwards. The disposal of these cases was as follows: (a) Schick negative—no treatment; (b) Schick positive and Moloney negative—1 c.cm. of A.P.T. (retest in five weeks); (c) Schick positive and Moloney positive—1 c.cm. of floccules (T.A.F.) repeated in two weeks and retest in five weeks.

All prophylactic injections were given by the subcutaneous route.

The majority of children under 7 are susceptible to diphtheria and it was felt that the exclusion of the preliminary test reduced injections to the minimum. Indeed the great virtue of immunisation by A.P.T. reposes in the claim that it is possible to protect children by a single dose, and if this claim can be substantiated a big advance has been made. In my experience no method involving the use of multiple injections can hope to achieve complete treatment for all cases attending, and it will be found that when the final tabulation is made con-

siderable leakage has taken place. In our case failures to complete treatment varied from 32 per cent in 1932 to 8.8 per cent in 1933. In 1935—the first complete year in which A.P.T. was used—the leakage was calculated to be only 0.72 per cent. A defection rate of 32 per cent is serious and any scheme characterised by such figures must be written down as a failure. The main, if not the only, cause of such failures is the objection inherent in so many people to hypodermic injections, and the reduction of such injections to the lowest possible minimum is therefore most desirable, especially if it can be shown that there is no reduction in the degree of protection conferred.

The group dealt with here comprised originally 3189 children, including 398 who were found to be negative to the preliminary Schick test and did not require treatment, and 634 others who received treatment but failed to come for the final Schick test. There is, therefore, a residual group of 2157 who received treatment and were Schick tested after it, and it is this group which is concerned in the analyses which follow.

Results of Treatment

It was decided in the first instance to review the results of the Schick test as a whole without any reference to the period that had elapsed between treatment and test, and the result is set out in Table I. With regard to the first age group (0-2 years) it has to be stated that the great bulk of the

TABLE I
Final Results of Schick Tests after Treatment

Age-group	Cases	Schick test		Proportion negative (per cent.)
		Positive	Negative	
0-2	446	7	439	98.4
2-4	889	6	884	99.4
4-6	516	5	511	99.0

8-10	60	3	61	93.0
Over 10	16	1	15	93.1
Total	2157	23	2132	98.7

children were over 18 months, as it was only in exceptional instances that we treated children under this age. The proportion of negative reactions varied from 99.4 per cent (in the 4-6 group) to 93.1 per cent (over 10), but in the latter group the number of children is so small that the resulting figures become unreliable. Taking the group as a whole, it is found that after treatment 98.7 per cent of the cases yielded negative reactions, which is at least as good a result as could possibly be hoped to be obtained with any prophylactic of the multiple injection type.

The question, of course, arises about the Schick conversion rate—i.e., the proportion of cases that have been converted from Schick positive to Schick negative. As stated above, primary tests were not performed in children under 7, who comprise the great bulk of the cases, and consequently a direct answer cannot be given in their case, but it is possible to adduce at least approximate figures. Since 1929 over 4000 children in Cork have been subjected

* The materials used by us throughout were supplied by the Wellcome Research Laboratories, Beckenham, and I am indebted to Dr R. A. O'Brien, the director, for supplies sent gratis in the earlier stages of the investigation. Four different batches were used the L.F. value of which varied from 20 to 50.

to the primary Schick test and it has been found (Ann. Rep 1935) that the proportion of positives has varied from 78.2 per cent. in 1929 to 44 per cent. in 1935. Differential analyses (according to age groups) have been made since 1932 and the proportion of positive reactors in 0-5 years group has varied from 88.4 per cent. in that year to 60.8 per cent. in 1935 and the corresponding variation in the 5-10 years group from 60.1 to 40.5 per cent. We may assume therefore that about 60 per cent. of the 1851 children who comprise the first three groups of our present series—i.e. 0-5 years—were positive before treatment. This gives us a hypothetical group of 1224 Schick positive children of whom (from Table I) 17 remained positive to the secondary test. Thus we have a conversion rate of 98.6 per cent. which is the same figure as the proportion of negative tests yielded by the whole group.

A further analysis was made according to the period elapsing between treatment and test. The result is shown in Table II. In all cases an effort was made to get the children to attend for the test at the end of five weeks. 840 of them did so. It will be noted that no less than 94.4 per cent. were negative at the end of this relatively short period. If one excludes the two last groups (8 years and upwards) in which the figures are again very small the result is even better: the proportion of negatives then varying from 90.4 to 99.4 per cent. This is important. It indicates a very high conversion rate in a very short time. As we proceed to the longer time periods we note a more or less progressive improvement in which the proportion of negative reactions is never less than 99 per cent.

These results are much better than we had previously experienced with toxoid antitoxin (three injections) the highest negative rate being 89.7 per cent. at a ten months' interval (1932) and better also than those obtained in a group of 1081 children treated by us in 1933-34 with potent formol toxoid (two injections). In this case the proportion of negatives on retesting was 90.8 per cent. (work not published). The nearest approach we have had to such figures was with the earlier batches of alum toxoid that I previously reported (1932) but in that case multiple injection was used. It would hardly be surprising if such figures as these now reported induced some degree of scepticism and in fact more than once during the course of this work I have felt inclined to call in question the potency of the

toxin used for the Schick test but any uneasiness on that score was allayed by the results of the primary tests which were carried out concurrently. The reactions which presented themselves were in every way normally developed among this class. The great majority of the readings were made by myself and such as I did not see were read by my assistant Dr P. F. FitzPatrick who has had considerable experience in this work.

OTHER WORKERS' RESULTS

It is clear therefore that in this area a single dose of A.P.T. has been very effective as an immunising agent, and it remains to be seen how the results obtained compare with those in other places. Some of these are shown in Table III.

Isabellinski, Judenitch, and Lowzow (1936) also describe interesting results obtained in guinea pigs in which the treated animals were found to be resistant to 600 m.i.d. of diphtheria toxin. Koster (1935) comparing the results obtained with toxin-antitoxin, formol toxoid (F.T.) and A.P.T. (see Table III) concludes that A.P.T. gives a higher percentage of immunity than F.T. in eight to nine weeks after treatment but that the immunity conferred by the latter is more enduring. Leach (1936) describes the results of field immunisation carried out in rural districts in Austria and experiments to determine the relative merits of different antigens. He believes that unless depot material is present on high value toxoid has inferior immunising powers. It was found that 60 per cent. of the antigen was eliminated by the kidneys in twelve hours. This author's findings confirm the earlier work of Glenn (1930) and are confirmed by those of Schmidt-Burkhardt (1936) who describes experiments on groups of guinea pigs which were immunised in parallel with crude form of toxoid, A.I. (O.H.), formol toxoid and A.P.T. (prepared by the method of Glenn and Barr (1931)). The latter two antigens were found to be much superior to F.T. and the better results are ascribed to the absorption of the antigen and its slow subsequent release during immunisation. According to this author both the alum preparations gave rise to fewer undesirable reactions than crude toxoid.

In regard to animal experiments special reference has to be made to the important work of Farnham (1936a) in which is described the results of inoculation of guinea pigs with A.I.T. and the subsequent operative removal of the inoculated tissue and its reinjection into the guinea pigs. In this method the animals are all to have that even thirty-eight days after injection in which we gave evidence of containing antigen. Immunisation of alum content of the tissues at the site of injection was found that the content remains practically unchanged for at least two days after injection. The higher the first antigen was left in situ the longer the antitoxin titre is maintained at high level. These results suggest that an active

injected in relatively insoluble form serves as both primary and secondary antigenic stimulus or indeed, rather, acts as a continuous stimulus Elsewhere (1935b) the same author describes field work in Hungary with A P T on a large scale (see Table III)

kn = known ms = months

The authorities so far quoted have expressed favourable opinions in regard to the value of A P T, but not all observers have been so favourably impressed.

Frazer and Halpern (1935) in comparing the antitoxin response to one dose of A P T and three doses of unmodified toxoid found that the response to the latter was distinctly greater than to the single dose of A P T. In the A P T group, after 10 weeks 62 per cent had more than 1/100 unit of antitoxin per c cm. Whereas of the toxoid group 91 per cent had more than 1/100 unit per c cm. After 1 year only 19 per cent of the A P T group remained above 1/100 unit (cf findings of Faragó referred to above) while 91 per cent of the toxoid group remained above that level. Lai (1935) obtained only 62.6 per cent conversion rate after 5 months in 359 previously Schick positive children, but, in this case, it is possible that the poor result was due to using an antigen of low immunising power (0 Lf). Pansing and Schaffer (1936) investigated the duration of immunity in groups of children who had received a single dose of A P T. In the first group 462 positives were retested 28 days after inoculation and 84 per cent were found negative. The second group consisted of 445 positives retested after 60 days in which 86 per cent had become negative. The third group comprised 549 children who had been given 1 c cm of A P T and subsequently found Schick negative. They were retested at the end of 2 years and 42.2 per cent only were found to be still Schick negative. In a smaller series of cases Parish (1936) compared the results after two injections and one injection respectively of A P T. In the former case an immunisation rate of 100 per cent was obtained as compared with 64 per cent in one instance and 81 per cent in another in the case of single dose A P T. He draws attention to the low natural Schick negative rate (17.5 per cent to 20 per cent) in the communities with which he was dealing and considers

that such communities are not suitable for treatment by the single dose method. Recently Bousfield (1936) drew attention to an extremely low conversion rate (37 per cent) obtained by him in a small group of children treated with 1 c cm of A P T.

It is possible that the explanation of the discrepancy that appears to exist in the findings of different workers with A P T may be found in differing natural immunity rates. Variations may also be due to differences in the "antigenic quality" of the preparation and in the strength and purity of the antigen. There certainly has been a striking change in the natural immunity level of children in Cork over a number of years.

Of 1170 children (all ages) submitted to primary Schick testing in 1929-30 there were 78.2 per cent of positives, whereas in 1934 when 1474 were similarly tested the proportion of positives had fallen to 44 per cent. Differential analysis according to age groups carried out since 1932 has shown all groups to be affected in the change, but it has been most pronounced in the 0-5 years group (88.4 per cent to 66.6 per cent). In the group over 10 years the proportion has declined from 37.7 per cent to 30.3 per cent.

For some reason, therefore, the natural immunity rate of children in this area has been considerably raised and now stands at a comparatively high level which, according to the views of Parish and others as set out in a leading article in the *British Medical Journal* (1935), is a favourable indication for the use of A P T by the single dose method and may possibly explain why we have obtained such good results by this method in Cork. But it does not explain the comparable figures obtained in many other areas as outlined above and I am inclined to believe that those who have had a considerable experience of A P T in actual field work will probably continue to use it among suitable groups of children.

EFFECT ON DIPHTHERIA IN CORK

In my original article on the subject (1932) I expressed the opinion that alum toxoid (A M T) was superior to toxoid antitoxin mixture (T A M) in the prevention of diphtheria, that it induced immunity more rapidly, and that in epidemic periods, when rapid induction of immunity is essential, it was the best antigen. Our experience of epidemic diphtheria in Cork has afforded a unique opportunity of testing the truth of these assumptions and I believe they have been verified by the facts. Reference to the diagram makes what follows easier to comprehend. It is a graphical record of diphtheria notifications (by quarters) from 1925 to the end of 1936, showing the introduction of T A M in June, 1929, A M T in June, 1931, and continued until December, 1932, when it was temporarily suspended. F T was introduced in March, 1933, and finally A P T in December, 1934. Although there was a considerable abatement in the severity of the epidemic after 1931 the real decline set in in 1935 and is clearly shown in the graph. In my opinion the main factor here was the large number of children (particularly of pre-school age) whom we were able to immunise by the single dose method. Very similar figures to these were adduced by Prof B. Johan at the second International Congress for Microbiology in London in July, 1936 in relation to diphtheria incidence in Hungary. He showed tables and diagrams illustrating the pronounced reduction in the incidence in certain areas after the introduction of A P T. Prof Johan advanced as one of the reasons for the failure of anatoxin to stem the tide of epidemic diphtheria in the affected regions the fact that quite large

proportions of children failed to present themselves for subsequent treatment after the first injection (see *Lancet* 1936 2 277). This will probably have been the experience of most people using the multiple-dose method. It certainly has been ours in spite of intensive following up. In the present series no less than 634 children failed to come for the final test. This represents the considerable proportion of 22.3 per cent. and in a scheme involving more than one injection such cases would have to be written off as failures so far as induction of immunity is concerned. In this respect, therefore, it is clear that A.P.T. marks an important advance in diphtheria prophylaxis and if it can be shown that a reasonable degree of protection is induced by a single dose this prophylactic should play an especially important part in combating epidemic diphtheria when rapid and widespread protection becomes an urgent necessity.

Reactions

The reactions experienced with this lot of A.P.T. have been definitely less than with the older batches used some years ago and this is especially so in regard to abscess formation. Our procedure was to instruct parents to report again in the course of three or four days if there was any anxiety on the score of sore arms or general sickness. Very few of them did so. In addition when the children reported for the

constructed. The standards used were those adopted previously when using alum toxoid:—

- 1 *Slight*—Local reaction not exceeding 1 in. in diameter either with or without slight malaise
- 2 *Moderate*—Local reaction 1-4 in. in diameter with or without malaise
- 3 *Severe*—Any local reaction exceeding 4 in. in diameter with or without general reaction

It is necessary to allude again to the fact that in this area these reactions are not regarded in the serious light that they appear to be in England and consequently the findings must be taken with a certain amount of reserve especially when reliance has had to be placed on the views of parents, but it has nevertheless been

remarkable what a very large proportion of mothers have been quite emphatic on the point that there were no reactions. It will be noticed that records of reactions of all sorts total 14.5 per cent. and that approximately 7 per cent. were mild, 5 per cent. moderate, and 3 per cent. severe. It will also be noted that the tendency to

Notifications in Cork City before and during immunisation with different agents

Total	150	69	101	46	6	28	313	14.3

Bellic test specific inquiries were made on these two points and where positive histories were forthcoming further more careful questions were put about the nature and extent of the reactions and from the information thus gained Table IV was

developed reactions were more marked in the older groups in spite of the selection of cases through the Moloney test. These results are a distinct improvement on those obtained in the earlier investigation (Saunders 1933) in which it was shown that reactions were experienced in as high proportions as 70 per cent. and 60 per cent. with different batches. In 5 cases in all of which the reaction was classified as 'severe' late development was noted. That is the first signs of inflammation were not noted until 6 or 7 days after the injection. Swelling was a characteristic feature of the inflammation in these cases. In 5 cases swelling without inflammation was noted. In these there was uniform swelling of the subcutaneous tissues of the outer aspect

of the upper arm but no sign of inflammation what ever. The swelling in such cases subsided in the course of a week. In none of 313 cases reported as having had reactions was there anything which gave rise to the slightest anxiety.

We did not find the Moloney test entirely helpful in picking out children who would not be likely to develop reactions with the prophylactic. As stated above all children over 7 were submitted to it and 670 such received the test. Of this number there were 286 Schick positives who yielded 153 Moloney negatives and these were treated with A P T. The results as regards reactions are shown in Table V. In 28 per cent reactions of varying degrees occurred.

ABSCESSSES

In this series there has been a remarkable freedom from abscess formation. Of the 2791 children who received injections of A P T only one case came under our notice.

This was a child, aged 5, who was brought by her mother three weeks after inoculation and then presented an abscess over the site of injection. Arrangements were made for treatment on the following day but it appears that the abscess "broke" itself that evening and the mother did not bother to take the child to hospital. The arm then healed spontaneously and when seen recently the child was perfectly well.

Apart from this case there has been a complete freedom from abscess formation. This is important as it seems to indicate that the makers have been largely successful in their efforts to produce an A P T which would be free from this unpleasant side effect. In our earlier series there were 4 abscesses among 579 cases (0.7 per cent). The results of other authorities are as follows—

	Cases	Abscesses	Per cent
Kositza (1935)	2013	19	0.9
Lai (1935)	489	1	0.2
Murphy (1935)	363	3	0.8
Naughten (1935)	370	1	0.3
Shafton (1936)	101	25	25

Faragó experienced 0.01 to 0.3 per cent in his series and Baker and Gill refer to light abscesses in about 0.04 per cent of a series of over 16,000 inoculations. Shafton's remarkable proportion is altogether exceptional and may be due to the presence of irritating non specific material in his toxoid.

INDURATION

It may be said that every case treated with A P T develops induration in some form. Every case examined by us within five weeks presented it. Varying degrees of size and hardness were experienced. In the great majority of cases the condition presented itself as a hard rounded mass, about 0.5 to 1 cm in diameter, lying in the subcutaneous tissues and freely movable. In some instances the form assumed was that of a small plaque varying in size from that of a shilling to sixpence. These indurations were not so permanent as those experienced in our earlier series and had disappeared in the majority of the cases seen after twelve weeks. In this respect, also, the antigen has been an improvement on the earlier batches.

Summary

1 A report is given of 2791 children treated with a single dose (1 c cm) of A P T.

2 Of this number 2157 were Schick tested at varying periods after treatment and 98.7 per cent yielded negative reactions.

3 Of 849 children who were tested in five weeks 94.4 per cent were negative.

4 Of 443 children tested at six weeks 99.3 per cent gave negative reactions.

5 At periods over six weeks in all cases the proportions of negative reactions were over 99 per cent.

6 A probable conversion rate of 98.6 per cent is assumed.

7 The proportion of cases who developed reactions was small (14.5 per cent of the total cases examined after treatment). Of these only 2.8 per cent were classed as severe.

8 In only 1 case was there any question of abscess formation.

9 Simultaneous with the administration of A P T there was a pronounced and apparently permanent decline in the incidence of diphtheria. It is believed that A P T played a significant part in this decline.

10 An alteration in the Schick status of the community has been noted and allusion made to the possibility of a high natural immunity rate playing some part in the good results obtained.

11 It is proposed to submit the cases to a further Schick test after a lapse of three years with a view to determining the permanency of the Schick negative state as induced by A P T.

MEDICINE AND THE LAW

Death after Ambulance Journey

THE St. Pancras coroner investigated last week a case where a patient, unable to obtain treatment at the hospital to which she was originally sent, died after a 25 mile journey to a second hospital. The deceased, a married woman aged 32, living at Slough, was taken to the King Edward VII Hospital at Windsor, she was due to have a child in about six days. She proved to have a septic infection, and at the inquest a medical witness explained that the hospital regulations do not permit cases of this nature to be returned in the

building there being no isolation accommodation. There was, he said, an isolation hospital for fever diseases at Slough but it was understood not to welcome cases of puerperal sepsis. The medical officer for Berkshire had an arrangement with the North Western Hospital in London whereby the latter would receive such cases from the Windsor hospital. The patient was therefore removed to the North Western Hospital but died within 24 hours of her admission. There was some difference of opinion among the medical witnesses over the patient's condition at the time of the journey. The doctor who examined her at Windsor on that day said she was not then suffering from general peritonitis; if she had been he would not have sent her away in spite of the hospital regulations. The pathologist who described the results of the post-mortem examination was of opinion that the infection was present for about four days before death. Asked by the coroner if the removal was desirable or not, he described it as deplorable. The coroner thought this adjective not too strong. He recorded a verdict that the patient died as a result of general peritonitis and that death was due to natural causes. This he said was not to imply that he felt satisfied with the removal. This unfortunate occurrence will doubtless lead to a review of the accommodation and arrangements in such emergencies.

Asleep at the Wheel

The Divisional Court has lately allowed an appeal against a stipendiary magistrate's decision that a motorist who had suddenly fallen asleep at the wheel of his car was not guilty of careless driving under Section 12 of the Road Traffic Act. The motorist was tired and as can easily happen dozed off. His car swerved and struck two trees by the side of the road. The magistrate took the view that the driver who is overtaken by sleep is in the same position as a person suddenly taken ill and is therefore not responsible for the results. It may be true as a general proposition of criminal law that an act unconsciously committed is not an offence—for instance if one can imagine a sleepwalker rising from bed and taking his car out on to the highway. The Divisional Court however lent no countenance to the view that a motorist who falls asleep at the wheel cannot be convicted of careless driving. The statutory offence under Section 12 is driving a motor vehicle without due care and attention or without reasonable consideration for other persons using the road. A motorist has a duty to keep awake and not to drive when so tired that there is a risk of his falling asleep.

Manslaughter and Negligence

The broader aspects of homicide by dangerous driving were considered by the House of Lords on April 22nd (Andrews v Director of Public Prosecutions) upon a special appeal by certificate of the Attorney General, from the Court of Criminal Appeal. The judgment delivered by Lord Atkin analysed the nature of manslaughter and made considerable reference to cases where doctors are accused of professional negligence. Andrews had killed a man on a well-lighted road when overtaking another car. He carried the injured man for a short distance on the bonnet of his vehicle then ran over him and failed to stop or to report the accident. The offence of murder contains though not exclusively the element of intention to kill. The offence of manslaughter on the other hand is based mainly on the

absence of intention to kill but the presence of an elusive element of unlawfulness. Where man slaughter is an unintentional killing caused by negligence, what degree of carelessness must be proved? Lord Atkin tracing the development of the law from the earliest times observed that at first there are judicial opinions which suggest that death due to any lack of care will constitute man slaughter. As manners softened and the law became more humane a narrower criterion appeared. People shrank from attaching the penalty for a felony (formerly a capital offence) to results produced by mere inadvertence. The narrower view continued. Lord Atkin became apparent in prosecutions of medical men or men who professed medical or surgical skill, for manslaughter by reason of negligence. He referred in passing to *R v Williamson* (1807) where a man who acted as a man midwife tore away a part of the prolapsed uterus mistaking it for the placenta. By a mistake in his observation of the actual symptoms the accused inflicted on the patient terrible injuries from which she died. Yet Lord Ellenborough held that to substantiate the charge of manslaughter the prisoner must have been guilty of criminal misconduct arising either from the grossest negligence or the most criminal inattention. It was on this occasion that Lord Ellenborough made an oft-quoted observation:

if the jury should find the accused guilty of man slaughter it would tend to encompass a most important and anxious profession with such dangers as to deter reflecting men from entering into it. Lord Atkin then passed to the modern case of *R v Bateman*. He cited Lord Hewart's dicta as to the distinction between negligence in a civil case and negligence in a criminal case. Lord Hewart had said that in order to establish criminal liability the facts must be such that in the opinion of the jury the negligence of the accused went beyond a mere matter of compensation between subjects and showed such disregard for the life and safety of others as to amount to a crime against the State and conduct deserving punishment. Lord Atkin was inclined to think that the ideas of crime and punishment do not in themselves help a jury to decide whether in a particular case the degree of negligence amounts to a crime and deserves punishment. But he observed that the substance of Lord Hewart's judgment in *R v Bateman* was most valuable and he thought correct. In practice it had been adopted by judges in charging juries in all cases of manslaughter by negligence whether in driving vehicles or otherwise.

The upshot of Lord Atkin's judgment is that recklessness can contain the element of negligence which justifies a charge of manslaughter; recklessness is a specific element in the offence of dangerous driving under Section 11 of the Road Traffic Act of 1930. Parliament has since enacted that on an indictment for manslaughter a man may be convicted of the lesser offence of dangerous driving; recklessness as an element of dangerous driving within Section 11 may amount but by no means necessarily amounts to the degree of criminal negligence requisite to establish the offence of manslaughter. The medical profession is only in lively concern in the penalties for careless or dangerous driving or in the subtleties of the history of manslaughter. It will however appreciate that Lord Atkin in the House of Lords has confirmed the decision of the Court of Criminal Appeal in *R v Bateman* so that there has been no relaxation of the high degree of negligence requisite to justify a verdict of manslaughter.

GRAINS AND SCRUPLES

Under this heading appear week by week the unfettered thoughts of doctors in various occupations. Each contributor is responsible for the section for a month, his name can be seen later in the half-yearly index

FROM A MEDICAL ECONOMIST

I

SOME years ago the late Sir Walter Fletcher told me that he had always wondered why it was so impossible for a doctor to discuss medical matters satisfactorily with a layman—"even a very intelligent layman." He expressed the view that the difficulty lay in outlook as well as in knowledge and training. In fact the layman's attitude to medicine is always strictly utilitarian. He looks upon his doctor as a man with a mission to cure disease and is apt to become impatient when other considerations are presented to him. Nor is he tolerant, as a rule, of a practice which excludes personality or individual predilection from its scope. He insists upon being cured as a separate and distinct human being and rejects vigorously the idea that any average therapy can satisfy his needs.

His choice of a doctor is determined by this attitude. He will assure you that he is fortunate in the respect that his medical adviser knows his constitution and has had experience of his family—knowledge and experience to which he attaches quite as much importance as to any professional attainment. Again, he will avoid, if possible, a doctor possessed of a reputation for giving the same drugs to all his patients or advising many of his patients to submit to the same surgical or specialist treatments. His doctor must not prejudice him. Obstetarily he refuses to become a mere number in a ledger or upon a bed.

I have heard this attitude described as vanity but, if so, then all men and all women are vain. A more interesting consideration is its merit. Is there, in fact, any substance in the contention of John Smith that he must be treated and cured as John Smith and not as an example of the average man? Again, is John Smith entitled to his view that his doctor must be, if not his friend, at least his father-confessor and familiar? We all repeat the assertion that the best treatment is to be obtained in great hospitals, but those of us who can afford to do so, go, often enough, to private nursing homes or private wards. Nor do we choose, necessarily, the most distinguished, academically, among our colleagues to see us through our illnesses. We are certainly not, in this action, casting any aspersions either upon hospitals or upon learned professors. Rather we are obeying an instinct which, in others, we are apt to deprecate as irrational.

What is that instinct? The Duke of Wellington stated on one occasion that the presence of Napoleon on a battlefield was equivalent to a French reinforcement of 50,000 men. The reference was not so much to the Emperor's genius as a commander as to the effect of his personality upon his soldiers. Each man became, in his presence, a being transformed. Napoleon was well aware of it, nor was he less well aware of the importance, in war, of those influences which he knew so well how to exert—patriotism, the will to conquer, the sense of a crusade, the thirst for glory. These "*imponderabilia*," as he called them, represented in his view the most important element of victory. His proclamations to his soldiers remain as the eloquent witness of his faith. Foch held the same opinion. His dispatch,

during the Battle of the Marne, remains a classic of leadership. "My centre is broken, my right recoils. All goes well. I attack."

What has this to do with the choice of a doctor? Everything. I remember still, after nearly half a century, the sense of ineffable relief and comfort which I experienced at the sight of our family doctor when any member of the family was ill. He was a very small man with an uncompromisingly bald head. But there was a look in his eyes which was worth the contents of a dozen chemists' shops.

* * *

Not that he failed to prescribe medicines. I have often observed that those men who, in any walk of life, are able to inspire confidence are almost always masters of the technique of their calling. Both Napoleon and Foch were superlatively good soldiers in the strictest professional sense, neither, had he been a doctor, would have missed a ruptured appendix or failed to make a diagnosis of diphtheria, and neither would have delayed to order the appropriate treatment. But technique, in the view of both, cannot be complete if the man himself is left out. Confidence and inspiration they insisted are the mountain peaks of technical efficiency. They would have so achieved, consequently, that their patients placed in them implicit and comfortable trust.

It seems to stand to reason that an influence which makes a man stronger and more confident than he was before he had experience of it must, similarly, exert effect upon every organ and every cell of every organ. Few dispute to day that healing, in the last issue, is by that *vis medicatrix naturæ* upon which the doctors of earlier days placed so much reliance. The greatest doctor perhaps is he who can most magnify, in his patient's body, the healing power of nature.

All this is commonplace, of course, but there is much forgetfulness of the commonplace. The assertion that, other things being equal, the doctor with the biggest practice must necessarily be the best doctor would scarcely go unchallenged among doctors themselves. But most laymen would accept it as obvious truth. And, in fact, Napoleon—to return to him—put it forward as a rational basis for any system of remuneration of doctors by the State. He was hotly controverted by his medical advisers but refused to change his mind. Indeed he pointed to Corvisart, his personal physician, as proof of his contention, saying that Corvisart was popular because he could cure persons whom other doctors had failed to cure. Corvisart's medical memoirs are ordinary enough and do not suggest that he was possessed of any special knowledge.

Medical achievement has been so great recently in the field of physical science that the science of men has tended to be overlooked or even despised as unworthy. So much so, indeed, that, as a clinical teacher declared some years ago, "they are all engaged in studying the molecular structure of steel in order to find out what a bicycle looks like." That may perhaps be another way of saying that any divorce of medical research from the bedside is fraught with danger. For, in truth, there is no such thing as disease, there are only sick men and women.

And it is the sick men and women who must be treated.

It was suggested recently that the human organism spends all its energies in reacting to stimuli every one of which in the absence of reaction would be lethal to it. On that showing and there is a substantial body of supporting evidence, the phenomena of disease are signs not as is often asserted of reaction but of failure to react completely. The sick man is like the man in panic: he cannot bring himself to face and overcome his trouble. That it may be is where the doctor really comes in. His strength and wisdom and skill are added to those of his patient so that the impossible may be accomplished. The doctor must necessarily fail where his knowledge fails, and in this truth lies the abundant justification of all research. But the fact remains that knowledge being equal one man succeeds where another can envisage nothing but calamity.

And thus certainly is great mystery. I think sometimes that our lively fear of falling into the abyss of the magical has blinded our eyes to the reality of the mysterious. Desperately we seek to explain in terms of cells what belongs only to organs and in terms of organs that which belongs to the body as a whole. Worse still we must force life into the measure of the dead house lest we confess to commerce with spirit. The endocrine complex is all very well but it does not explain the influence of man upon man or more mysterious still of man upon himself through faith. Science it would seem is no more free from the temptation to play Smart Alec than is any other branch of human activity.

It must resist that temptation and the best tonic of resistance is without doubt that sense of the mysterious which so conspicuously informed the minds of for example Pasteur and Lister. As was said by the Rusticating Pathologist in these columns to hand on the present system of knowledge as if it were a system of revealed truth is a travesty of education of university standard.

The doctor indeed ought to go to school with the priest and the soldier both of whom have much to teach him. Lord Baden Powell told me years ago that his secret is the enlisting of a boy's native enthusiasm. Once that has been set to work so to speak a real physical culture—as opposed to physical jerks—becomes possible. For enthusiasm compels the lad to submit to the hard discipline of training which enthusiasm has recognised as the prerequisite of efficiency. It is the same in the arts and crafts. All these impose the fierce discipline of the raw materials the morality of things as opposed to the morality of ideas. None lacking enthusiasm will endure so stern a schooling. The doctor's raw material is humanity not an incoherent mass but a body of persons each sharply differentiated from all the others. The discipline imposed by them is stern so that nothing but the love of them can make it endurable. You may call this vocation or enthusiasm of its reality and its necessity you cannot beyond a very early age remain in doubt. What the patient asks for above skill and knowledge is sympathy dedication sacrifice in the classic meaning of that word. Nor will a wise man rest until he has found it for therein is the only true healing.

PANEL AND CONTRACT PRACTICE

The Capitation Fee

LAST year the Panel Conference asked the Insurance Acts Committee to open negotiations with the Ministry of Health for reconsideration of the capitation fee of 9s. awarded by a court of inquiry in 1924. A deputation waited on the Minister and pointed out that the amount of work that insurance practitioners are called upon to do has substantially increased during the past twelve years. The Minister said he thought that a flat rate below the present figure could well be justified, but since there was a difference of opinion he was willing to arrange for arbitration. A similar difference of opinion it will be recalled arose over the capitation fee to be paid for persons under sixteen years of age when these are brought under the National Health Insurance scheme and the council of the British Medical Association report (*Brit. med. J.* April 24th 1937 Suppl. p. 218) that they have had no further communication from the Ministry about this. They understand however that the arbitrators to be appointed will be asked to say what in their opinion should be the appropriate fee for medical attendance on all sections of the population.

Negligence and the Sequel

The London Medical Service Subcommittee has not had to meet between December and April which we understand is a record vacation but they have had now to consider three cases, one in which no evidence of failure on the part of the practitioner was adduced, one in which an insurance practitioner was led to issue two certificates without examining the

patient who was actually in hospital (this was one of those cases of importunity by a financially embarrassed wife and will probably cost the unfortunate doctor £2) while the third has been the subject of considerable attention by the lay press.

On Dec. 30th 1936 an insured person became ill and took his temperature which was 103° F. He lived in a flat in a block of such dwellings and his sister in law who was looking after him while his wife was in hospital telephoned for the practitioner at about midnight. She spoke to the caretaker of the house in which the practitioner lives and being told that the practitioner was out she again telephoned about 1 A.M. with a like result. She told the subcommittee that on each occasion she gave the name of the patient his address and the exact location of the flat close to a well known hotel in the city, also that the patient seemed to be seriously ill. According to the practitioner he returned home between 1 and 2 A.M. and found a note that he was wanted at X House to which he proceeded finding the house in darkness and obtaining no reply to his rings at the bell. He said he went again about 8.30 A.M. and was then told by the managers that no request for his services had been made from that address. He telephoned home but was assured that the managers indicated that he was wanted at X House. In point of fact the insured person resided at X House. The subcommittee's report says that admittedly the names of the two establishments are not dissimilar and might be confused over the telephone but they lie some distance apart and they had no hesitation in accepting the statement of the relative that she was at pains when telephoning

to explain the exact location of the house, and that the directions were repeated to her. The practitioner did not attend his morning surgery at all on Dec 31st but said he was visiting patients until 6 P.M. Further telephonic applications for his services were made at 8.45 A.M. and at two or three other times during the morning, but although the caretaker asked another practitioner to visit the patient he was unable to do so. Eventually the practitioner saw the patient at about 8.15 P.M., but by then another doctor had been called and had ordered the patient's removal to hospital, where he died some eight hours later.

The practitioner told the medical service subcommittee that it was the practice of his caretaker to note the addresses from which the requests for visits came, but not the names of the patients concerned. The comment of the medical service subcommittee on these statements was as follows: "The practitioner's explanation that he was unable after two fruitless calls at 'X House' to refer to the record card for the true address because the caretaker was not in the habit of recording names, or, as it appeared from the practitioner's answers to us, even the number of the tenement, in a block of tenements, seems to us, if it is true, to point to a lack of method in carrying on his practice, which would be nothing less than appalling. His failure to offer this explanation when he did visit 'Y House' (where incidentally he enquired for the patient by name) is a strong indication that the explanation is not worthy of credence. We say this with much regret, but we should frankly still more regret the condition of things in this practice if the explanation were true." The committee decided to censure the practitioner, to require him to assume responsibility for the expense incurred in calling in another doctor, and to ask the Minister of Health to withhold the sum of £20 with a view to the deduction of a corresponding amount from the remuneration of the practitioner (who has, however, the right to appeal to the Minister). The committee have also decided to consider action under regulation 35 (2) (a). This regulation provides that if the committee are satisfied that owing to the number of persons included in his list a practitioner is unable to give adequate treatment to all of them, they may, after consultation with the panel committee, impose a special limit on the number of insured persons for whom the practitioner may undertake to provide treatment. In that event any number in excess of that limit shall be dealt with as though the list of the practitioner was by that number in excess of the general limit fixed for the list of practitioners in the area. The insurance committee decided to refer this case to the appropriate subcommittee to consider whether the normal maximum of 2600 insured persons should be reduced. Clearly consultation with the panel committee will take a little time and a question arises as to possible appeal. This particular practitioner has a list which is approaching the maximum and if a lower limit is fixed for him, it will of course mean that his insurance remuneration will be reduced. If, for instance, the committee decide that a limit of, say, 2200 should be applied to this practitioner, it will mean that his potential yearly insurance income will be reduced by about £135. The practitioner might feel that it was undesirable to appeal against the withholding of £20 in respect of the negligence found in the specific case but the prospect of losing part of his annual income might well lead him to appeal to the Minister. If, in fact, the committee after consultation with the panel committee, decides on a lower limit, as part of the decision in the case, the period of one month

during which the practitioner may appeal will doubtless be regarded as beginning when notification of the decision for or against a lower limit is sent to him.

IRELAND

(FROM OUR OWN CORRESPONDENT)

A NATIONAL SERUM INSTITUTE

Dr C. J. McSweeney has been speaking to the Royal Academy of Medicine on the need for a National Serum Institute in Ireland. At present, he said, there are no manufactures of serums for diagnostic or therapeutic purposes in Ireland, and in the present state of Europe this position is not free from danger, for national emergencies elsewhere might lead to a shortage of supplies. Apart from this, serums prepared from strains of micro organisms prevalent in other countries cannot be expected to be as potent in Ireland as serums from the native strains. The fatality rates for such diseases as diphtheria and cerebro spinal fever are consistently higher in Dublin than in cities in Great Britain, even when similar treatment and dosage were employed. Dr McSweeney suggested that this difference of results may be due to a lesser efficacy of the serums made from strange strains. An institute such as he suggested would serve as a centre for investigation and research into problems relating to serum therapy and prophylaxis. If it were to be established it could most fitly be associated with the new Dublin Fever Hospital scheme, and, in such circumstances it could undertake the task of preparing an adequate supply of human immune serums for the prophylaxis and treatment of such virus diseases as measles and poliomyelitis. Convalescent donors would be numerous enough to permit the issue of serums so prepared to private practitioners. The institute, if established, should be in close association with the recently established Medical Research Council and with the medical schools of the country. It should not be given a monopoly in the manufacture of serums for the Irish Free State, nor should it have power to interfere with the business of the many reputable firms which market their biological products there. He thought it would be possible to find the necessary finances from Hospital Sweepstakes funds.

Prof J. W. Bigger, the next speaker, emphasised the importance of such an institute from the points of view of education and research. While approving of the establishment of a serum institute, he would oppose its being under State control. State activity was seldom progressive and State control tended toward parsimony even where expenditure might be necessary. An institute would be expensive for the services it could hope to render. In the discussion which followed there was general agreement that the establishment of a serum institute deserved consideration and investigation, and it was agreed to invite the General Council of the Royal Academy of Medicine to take appropriate steps. There was a consensus of opinion that if established the institute should be free of Government control, and that one of its main objects should be the promotion of research.

CHARING CROSS HOSPITAL.—Mr Philip Inman, speaking at the annual general meeting of the court of governors of this hospital, said that it was hoped to rebuild in or near the present site. The income for 1936 was a record one, £85,729. The expenditure was £71,143.

PUBLIC HEALTH

THE INFLUENZA EPIDEMIC IN
RETROSPECT

As judged by the number of deaths attributed to influenza in the 122 Great Towns of England and Wales the epidemic period of 1930-37 may be said to have been roughly from the beginning of December 1930 to the end of March 1937. The secular trend of the epidemic as judged by mortality in these towns (the only general numerical data we possess) is shown in the Table and diagrams below. In the

Deaths from Influenza in the Great Towns

Week ending 1935	Deaths	Week ending 1936	Deaths	Week ending 1937	Deaths
Dec 3rd	32	Dec 4th	45	Dec 5th	43
10th	68	14th	62	12th	64
17th	85	21st	67	19th	67
24th	120	28th	60	26th	97

25th	65	21st	80	20th	171
Total	10 621		1185		7570

seventeen weeks between the beginning of December 1930 and the end of March 1937 the number of deaths registered as due to influenza reached the total of 7570. This number may be compared with the 1465 in the same period of 1935-36, a normal non-epidemic year and the 10 621 in 1932-33 the last epidemic year.

Although on a lower scale than this last wide out

FIG 1.—Graph showing weekly total death from influenza in the Great Towns in three different years.

break, the recent epidemic as judged both by mortality and by the available evidence of widespread incidence, must undoubtedly be added to the list of major visitations to which the country has been subject since the beginning of the century. In its

FIG 2.—Weekly deaths from influenza in the Great Towns per million of estimated population.

time of onset and of maximum mortality it closely resembled the epidemic of 1932-33 but its rate of decline has been relatively slower. The age distribution of mortality was of the type usually described as normal that is the greater share was borne by persons well on in years and relatively little by young adults. With the exception of the Welsh towns which appear to have escaped rather lightly there is little evidence from the mortality figures of the epidemic bearing more heavily on one part of the country than another. The death rates from influenza between December and March vary but little between the different regional areas. There was however some considerable difference in the time sequence of the epidemic trend. In London both the central area and the environs the maximum mortality fell in the week ending Jan 10th and in the remaining towns of the south-east the peak came only a week later. In the northern midland and south western towns it was not reached till the last week of the month and in the eastern and Welsh towns the total continued to rise till the end of the first week of February. In general the figures show the epidemic progressing from the south to the north and radiating at the same time to the east and west.

The Health Reports of the League of Nations show that in Germany the epidemic occurred some weeks earlier between the middle of November and the third week of December. Its incidence was falling there at the same time as it rose in the southern area of England. In the U.S.A. its course appears to have been broadly parallel with that in this country. Many other European countries show evidence of epidemic prevalence and in the majority of them the peak had been reached before the end of January. There is little else to add. The work now in progress at the National Institute for Medical Research and elsewhere gives us much hope of the final production of an efficient vaccine such as might tide the population over these few weeks of sudden and universal epidemicity. Such protection might well reduce the ravages of outbreaks which we now seem destined to endure every few years.

CORRESPONDENCE

AMBULANCES AND STRETCHERS

To the Editor of THE LANCET

SIR,—In his letter on this subject in your last issue Surgeon Commander Ford advocates a standardisation which is obviously overdue. He suggests that as the majority of stretchers are of the long type it is desirable "to encourage the production of long ambulances only."

The long ambulance may be all very well for public authorities but there are large numbers of firms using ambulances for industrial accidents and the long ambulance is inconvenient and more costly. Surely it would be much better to standardise the stretchers with telescopic handles. After a few years of this standardisation the vast majority of stretchers could easily have been converted to the telescopic or short handled type.

Surgeon Commander Ford has omitted to mention the other important factors in standardisation—namely, the wheel base, wheel diameter, and gauge of the stretcher wheels to enable them to run on a standardised track on the ambulance racks. In addition it is very necessary that hospital casualty trolleys should be similarly standardised. A very little investigation will show how standardisation of one particular is quite useless unless all the factors in stretcher construction are worked to a common specification. I urged this in a letter to your columns two years ago (*Lancet*, 1935, 1, 574). At the moment however stretcher manufacturers and ambulance makers are continuing to act with a sweet individuality which may make it necessary to shift a seriously injured patient as many as three times between the location of the injury and his arrival in the ward. This is entirely unnecessary and quite absurd.

In advocating the retention of the long type stretcher has Surgeon Commander Ford considered that passenger lifts and railway carriages will not permit the long handled type, whereas the telescopic-handled type of stretcher can be fitted in almost anywhere? To my mind there is no possible alternative but that the long handled type of stretcher should be abolished.

I am, Sir, yours faithfully,

Beeston Notts April 23rd

L P LOCKHART

ERADICATION OF BED-BUGS

To the Editor of THE LANCET

SIR,—The article by Mr. Ashmore and Mr. McKenny Hughes in your issue of Feb. 27th, on the use of coal tar naphtha distillates in bed bug control, draws attention once more to a serious problem. In spite of improved standards of living *Cimex lectularius* is still spreading, mainly through the introduction of infested furniture into new premises.

An agent employed against bed bugs should if possible be (1) cheap, (2) toxic to the insect, (3) not toxic to man and animals, (4) non inflammable, (5) easy to apply, (6) readily available, and (7) free from residual odour and not injurious to the premises disinfested. Further (8) its use should not involve much preliminary preparation. How far do coal tar naphtha distillates fulfil these conditions?

1 *Cost*—Their present cost is only about 2s 6d per gallon.

2 *Toxicity to insects*—Since the naphtha fraction forms a toxic vapour the liquid apparently need not

come into actual contact with the insects in order to kill, though in the method described it appears to be applied both as a contact insecticide and as a fumigant. Experimenting with a naphtha fraction of the same boiling range, I found that the vapour has a rapid action on bed bugs, but that those receiving a sublethal dose rapidly recover. At the concentration specified (one gallon per 750 cubic feet) in glass containers, an exposure of six hours at 73° F did not produce a 100 per cent kill using third and fourth stage nymphs. After only two hours' exposure all the bugs recovered, and after four hours, 75 per cent. In each case all insects were apparently moribund after removal from the containers. The same concentration was found to be ineffective against the eggs in all stages of incubation, there being a 100 per cent hatch after six hours' exposure under the same conditions. Although the exposure time was only six hours against 18-24 as recommended, the greater resistance of eggs than nymphs to naphtha is shown.

3 *Toxicity to man and animals*—Although the saturated atmosphere has been proved to be relatively non toxic to animals, gas masks must be used during fumigation. The possible occurrence of mesitylene, which has been found to be toxic to man, must be considered. This chemical, having a boiling point of 165° C, would, if occurring in the crude naphtha, be present in the fraction mentioned (distillation range 180°-190° C approximately) after distillation. Local government officials and others might be led to imagine that any coal tar naphtha fraction coming within the distillation range specified would therefore be satisfactory. Gas works and other sources of supply, while endeavouring to keep down the cost of the product, might fail to remove mesitylene from the fraction.

4 and 5 *Inflammability and ease of application*—The fraction specified was stated to have a flash point of not less than 105° F. When applied by means of a sprayer, the flash point of the fraction would be even lower in the atomised state. The fire hazard is, therefore, great, and it is doubtful, even with premises carefully sealed after fumigation, if it would be safe to have a naked light outside the room. There might also be a danger of explosion due to static electricity, when the fraction was applied by means of a pressure sprayer. Spontaneous combustion of petrol vapour has been found to be caused by static electricity, the risks being greatest under conditions of low relative humidity. Such an explosion might do much damage, and the attitude of fire insurance companies must be considered.

The volatility of naphtha decreases rapidly with decrease in temperature, but the resistance of the bugs increases with decrease in temperature. It is emphasised that fumigation should not be attempted at temperatures below 60° F, and pre heating of the premises by means of stoves should always be adopted, except in hot weather when the room temperature is above 70° F. This is a serious drawback, especially as the temperature cannot be maintained after the room is sealed, because the stoves must be removed owing to the risk of fire. The utmost caution must be observed when applying naphtha, and the employment of well trained men is desirable. The vapour is heavier than air, and tends to settle in the room whereas the bugs are often located in ceiling cracks. Thus measures must be taken to ensure distribution and concentrations far above those actually needed to kill bugs in sealed containers are necessary. In fact, the amount mentioned by Ashmore and McKenny Hughes is ten times the lethal dose, although the conditions were not stated.

6 *Availability*—There would be no difficulty in obtaining large supplies of naphtha from gas works and other places, but as I have said already, it is well to know the nature and percentage of toxic constituents in the fraction.

7 *Odour*—Naphtha has a very penetrating odour. This is an objection for it is undesirable for the sufferer to have to broadcast the fact that his premises are infested, and some vapour must escape before the rooms are sealed.

8 *Preparation of premises*—As with HCN fumigation removal of tenants and subsequent ventilation are required.

Though naphtha is not so poisonous as cyanide and the vapour is stated to clear after a few minutes, the premises must be thoroughly aired.

With vacant houses the difficulty of finding temporary accommodation does not arise but the attitude of tenants faced with temporary removal while their rooms and furniture are disinfested often prejudices local government officials against fumigants. Apparently with naphtha it is not thought necessary to remove all furniture, curtains &c. since the vapour is said to penetrate at least as far as the bed bugs secrete themselves. This is somewhat surprising because even when HCN is used the furnishings are normally removed for van fumigation, or steam disinfection in special chambers.

It will therefore be appreciated that in the practical application of an insecticide whether against bed bugs, cockroaches or other insects the toxicity to the insect is only one of many points to be considered. HCN is known to be very toxic to bed bugs (adults, nymphs and eggs) but it is so poisonous that it can be used only by experts. Naphtha however also has limitations that make it far from ideal as an insecticide.

There appears to be a place for an insecticide which the tenant or other user can apply himself. This introduces contact insecticides proper. The past few years have seen the development of certain contact insecticides for use against household pests fulfilling the desiderata stated at the beginning of this letter. They are mainly vegetable extracts which although non-toxic to man and warm-blooded animals, are very toxic to insects. Their toxicity to insects has lately been increased by the addition of certain organic materials harmless to man.

These insecticides must come into actual contact with the insect in order to kill. They are usually in the form of liquids applied by pneumatic sprayers so as to produce a mist of finely divided droplets which under high pressure can be forced to penetrate behind loose wall paper and behind cracks in skirting boards. This type of disinfection can be applied at a fraction of the cost labour and time of cyanide fumigation and without danger to the occupier or operator.

When the extracts are dissolved in an odourless kerosene base of high flash point the fire risk is negligible. Too heavy an oil base is however undesirable because there is danger of staining due to its low volatility. Increased freight costs are likely to be incurred on liquids below 150° F. flash point (see Railway Dangerous Goods Regulations) and similar regulations applying to inflammable liquids sent by road have now been introduced. High transport costs are therefore another point to be considered before adopting a new insecticide for use on a large scale.

There is no doubt that with fumigation enormous wastage occurs not only in absorption but in adsorption. Bed bugs are rarely found crawling on the walls in day time unless they are in very large numbers. The great majority are hidden in cracks behind loose wall paper, behind skirtings and in the framework of bedsteads and seams of mattresses and furniture. Fumigation is impartial; the fumigant cannot be concentrated on such hiding places thus there must be wastage. On the other hand when using a contact insecticide in the form of a finely atomised spray from a good pneumatic hand sprayer or preferably an electric sprayer most of the insecticide can be directed on to the walls and into cracks rather than into the actual room space and a smaller volume of liquid suffices. Whatever method is adopted—fumigation or contact insecticide spraying—

the room should be cleared beforehand and the furniture dealt with separately either by steam or cyanide fumigation. The best time to disinfect is after the room is stripped and before redecoration.

I am Sir yours faithfully

KETOGENIC DIET AMONG ESKIMOS

To the Editor of THE LANCET

SIR,—I have recently returned from East Greenland where I lived for fifteen months as medical officer to L. R. Wager's British East Greenland Expedition 1935-36. We were a party of seven Europeans and fourteen Eskimos (increased by one by the end of the year). During that time I was consulted by an Eskimo woman of about 40 years of age who was suffering from frequency of micturition and scalding pain on passing her urine. I examined her urine and found that she had a *B. coli* infection. She told me that she had had several attacks in the past but that this attack did not seem very amenable to treatment. On asking of what her treatment consisted, I learnt that she had been eating very large quantities of blubber which is the fat of the seal. It appears that this treatment is traditional among the Eskimo colony at Angmassalik although I do not know how frequently the condition occurs.

I should perhaps state that contrary to normal belief the Eskimo does not live on a very high fat diet although he does live on a low carbohydrate diet; he is not continually eating blubber but normally eats about as much fat with his meat as we eat with a grilled chop, that is to say that although the total fat diet per day is higher than that to which we are accustomed the protein fat ratio is about the same as ours.

In view of the modern treatment of cystitis by the ketogenic diet and mandelic acid this traditional treatment of the Eskimo seems to deserve notice.

I am Sir yours faithfully

L. C. POUNTAINE.

SHORT WAVE THERAPY

To the Editor of THE LANCET

SIR,—May I draw the attention of your readers who are interested in short wave therapy to the following quotation from a report recently issued by the American Council of Physical Therapy—a body which should certainly have its counterpart in this country.

Much of the work of this Council in the past year has been confined to the consideration of so-called short-wave diathermy machines. In view of the deliberations the Council believed it was justifiable to state based on the present available evidence the following conclusions: (1) There is no specific biologic action of high frequency currents. (2) There is no specific bactericidal action. (3) The therapeutic effect is due to the heat produced. Elaborating these three conclusions the Council felt that the general practitioner should understand that when he buys a short wave diathermy machine he is purchasing an apparatus capable of producing heat. In the light of available evidence it has absolutely no other specific action.

H. J. TAYLOR.

PRURITUS ANI

To the Editor of THE LANCET

SIR,—In the paper on pruritus ani which appeared in your issue of April 17th Mr Riddoch says "I hope to show that idiopathic pruritus ani is caused by oedema of the perianal skin, following on stasis in the external hæmorrhoidal veins, in other words, it is due to external piles." He mentions that X rays as a remedial agent appear to have some curative value but does not refer to radium, although the pathological condition described is one in which this agent should prove beneficial to the extent of producing a cure even in persistent cases.

The fact that X rays did not fulfil all the hopes that were entertained for them in this condition does not necessarily preclude the success of radium.

I am, Sir, yours faithfully,

RALPH H BROWNE CARTHEW

INFECTION THROUGH THE OLFACTORY MUCOSA

To the Editor of THE LANCET

SIR,—The leading article in your issue of April 10th is misleading as regards the passage of pigment granules through the tissues. This follows an assumption by Rake that a mixture of iron ammonium citrate and potassium ferrocyanide solutions constitutes a suspension of Prussian blue, which it does not. Rake's papers (*J exp Med* 1937, 65, 303, *Proc Soc exp Biol* 1936, 34, 716) contain several references to pigment, granules, or particles. For example, "prussian blue particles pass rapidly from the surface of the olfactory mucosa and within two minutes are found in the perineural spaces of the olfactory nerve fibres and in the subarachnoid space." He misinterprets Le Gros Clark in saying that he "considered that the granules had reached the olfactory bulbs mainly by passage along the perineural spaces." Le Gros Clark tried various particulate dyes (trypan blue and Indian ink) but in no case could he demonstrate the passage of particles from the nose to the brain. Both he and Rake used chemical solutions which were precipitated by acid in the tissues only after absorption. Rake uses his supposed passage of particles through the olfactory mucosa to the subarachnoid spaces in support of his studies of the passage of organisms from the nose to the brain, but as he used bacteriological methods only, such need further confirmation.—I am, Sir, yours faithfully,

F. A. PICKWORTH.

PRISONERS AND CAPTIVES

To the Editor of THE LANCET

SIR,—Whilst fully appreciating the kindness and human sympathy shown in the writings of your contributor Taddygaddy, I feel that in your issue of last week he allowed himself to be unnecessarily provocative. Had he paused to reweigh his "Grains and Scruples" I am sure that he would have avoided what can only be taken as severe criticism of a considerable section of his medical colleagues. His "unfettered thoughts" have allowed him to wander into the realms of fantasy. Surely it is unnecessary and unhelpful to attempt to arouse from its grave the voluntary hospitals' claim to monopoly of human feelings which died of inanition many years ago! On behalf of those who have the responsibility of

the care and treatment of the mentally deficient and the mentally ill I wish to register a strong protest against the attempt to build up prejudice against mental hospitals and institutions. I feel sure that your contributor would be persuaded to change his antiquated opinions if he would accept the invitation of any of my fellow medical superintendents or myself to come and move freely among our patients. He would run no risk of remaining "cut off and forgotten"—I am, Sir, yours faithfully,

W GORDON MASEFIELD

Brentwood Mental Hospital, Brentwood,

POSTURAL DEFORMITIES OF THE ANTEROPOSTERIOR CURVES OF THE SPINE

To the Editor of THE LANCET

SIR,—Mr Philip Wiles, in your issue of April 17th, touches on the value of certain exercises used in ballet training.

The system on which the ballet dancer is trained is a highly technical arrangement of fundamental exercises leading to the elaborations familiar to all. They are taught always in the same order, the subject holding a fixed bar with one hand, the other being free to move. This training at "la barre" is in accord with Mr Wiles's thesis in that, although to the spectator it appears that the exercise is being done by one leg whilst the subject stands on the other, in reality the work being done on the supporting side of the body is an apt illustration of Mr Wiles's "absence of movement." To maintain the upright position characteristic of the ballet dancer whilst performing extremely taxing movements with one leg requires strong adjustments throughout the whole body. By the perpetual repetition of these adjustments in successive exercises, changes can be effected in posture not possible in my opinion, by other methods in use at present. The technique is powerful, and so has its dangers. For this reason it is probably advisable that its remedial application be confined to medical gymnasts with ballet training, who are therefore able to make necessary modifications according to individual needs.

I think that Mr Wiles is too optimistic in maintaining that it requires but little ingenuity to invent a remedial system once the principles are understood. Systems come and go. To live they must have an inherent creative quality (the ballet technique has survived some 300 years because it has this). Posture exercises must have some primitive and/or aesthetic value—a potential, if not actual, emotional quality.

I am, Sir, yours faithfully,

CELIA SPARGER, C S M M G

London, W April 23rd

THE NEW WESTMINSTER HOSPITAL.—Part of the new Westminster Hospital, now being built on the St John Gardens site in Westminster behind the Abbey, will be known as the Coronation Wing, and by gracious permission the first ward in this will be called the King George the Sixth Ward. The total cost of building the wing will be £30,000. It will contain two wards of eleven beds each, and several rooms ancillary to the service of the wing, including a small pathological laboratory for quick examination. Nearly £20,000 has already been contributed towards the cost of this wing. Among recent contributions are two gifts of £1000 from "Aged 77." Mr Bernard Docker, chairman of the hospital, received the second £1000 from the same generous donor this week. An alderman of Westminster and governor of the hospital has also marked his appreciation of the project with a gift of £1000.

THE SERVICES

ORGANISATION OF THE INDIAN MEDICAL SERVICE

On April 8rd we gave an account of changes in the organisation of the Indian Medical Service. The *London Gazette* for April 20th contains a Royal Warrant amending the current rules for the promotion and precedence of the service. It is provided that the director-general shall hold the substantive rank of major-general or when approved by the Secretary of State for India of lieutenant-general. The ranks of the other officers shall be colonel, lieutenant-colonel, major, captain and lieutenant. A captain with at least six years service a major or a lieutenant-colonel may be promoted to the next higher rank by brevet. Officers will be placed on the retired list when they attain the following ages: major-general 60; colonel and brevet colonel 57; lieutenant-colonel and major 55; but a lieutenant-colonel who entered the Service before May 1st 1811 and who has been specially selected for increased pay may if he attains the age of 55 years before he completes 27 years service for pension be retained until completion of such service. An officer retiring on pension before completing 30 years service will be liable, till he attains the age of 55 to be recalled to duty in case of emergency. Six of the most meritorious officers on the active list will be named honorary physicians to the King and six honorary surgeons. On such appointment officers below the rank of colonel may be promoted to the brevet rank of colonel.

Major-General Ernest William Charles Bradfield O.I.E. O.B.E. M.S. Lond. F.R.C.S. Edin. I.M.S. Hon Surgeon to H.M. The King is now Director-General Indian Medical Service vice Major-General C. A. Sprawson O.I.E. K.H.P. I.M.S. retired.

Lt-Col J. F. James I.M.S. retires.

The Commander in Chief in India has made the following appointments:—

Lt-Col J. J. D. Roche R.A.M.C. as Assistant Director of Hygiene and Pathology Western Command Headquarters.

Major J. H. G. Hunter R.A.M.C. as officiating Surgeon to the Commander in Chief.

Major T. W. Davidson R.A.M.C. as Specialist in Radiology Peshawar District.

ROYAL NAVAL MEDICAL SERVICE

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lt. Comdr H. M. Willoughby to *Southampton*.
Surg. Lt. M. I. Reddington to *Imbroke* for R.N. Hoep. Chatham.

Surg. Lt. (D) R. S. Daly promoted to Surg. Lt. Comdr (D).

Mr A. K. Kerr of St. Ives, Cornwall has been appointed Admiralty Surgeon and Agent for St. Ives.

ARMY MEDICAL SERVICES

Col. C. M. Drew D.S.O. late R.A.M.C. having attained the age for retirement is placed on retd. pay.

Lt. Col. and Bt. Col. J. A. Mansfield D.S.O. from R.A.M.C. to be Col.

ROYAL ARMY MEDICAL CORPS

Maj. R. R. G. Atkins M.C. to be Lt.-Col.
It is to be Capt. R. J. G. Morrison J. W. Orr & C. London C. I. Watson J. A. G. Carmichael W. G. Paterson A. T. Mearns H. R. Simon A. C. Byles J. A. Hamilton J. Shields C. W. Maisey W. T. M. Moore K. H. Harper T. W. W. D. Avey M. E. Kelleher I. J. Crowe and C. McGrath.

It is (on prob.) R. J. Niven and S. H. Gibbs are restored to the establishment.

ARMY DENTAL CORPS

Short Service Commission F. K. Johnson to be Lt. (on prob.)

ROYAL AIR FORCE

Flight Lt. H. J. Melville is transferred to the Reserve Class D.
Flying Offr. H. C. de B. Milne is promoted to the rank of Flight Lt.

DEATHS IN THE SERVICES

The death occurred on April 24th in London of Major General Sir Thomas Lamb C.B. K.C.M.G. He joined the Army as surgeon in January 1886 became major R.A.M.C. in January 1898 lieutenant-colonel in 1906 colonel in March 1915 and major-general in 1917. He was temporary surgeon-general (without pay and allowances of the rank) while a D.M.S. in August 1916. He served in the European War from 1914 as an A.D.M.S. and D.D.M.S. of the Mediterranean Expeditionary Force. He was mentioned in dispatches and created C.B. (Mil.) in 1915 and K.C.M.G. in 1917. He was Inspector-General of Medical Services at the War Office from 1918 to 1921 (See p. 1080 for the Obituary Notice).

THE LANCET 100 YEARS AGO

From a leading article May 6th 1837 p. 232

In the two great endowed establishments of Southwark it is even determined by a written rule that no person is eligible to be a surgeon to the hospital unless he have served an apprenticeship with one of the surgical officers of the establishment. This is what is called an attempt to make the profession respectable that is to say by making it expensive and by restricting the selections of genius and talent which are to be displayed in the upper ranks of the profession from the more respectable and wealthier persons in the upper classes of society.

In pursuance of the same system we find that the hospital surgeons are permitted by the governors to charge each student twenty or thirty guineas for the mere privilege of walking through the wards of the hospital. Then, again, the use of the patients having broken, dislocated and ulcerated limbs is actually sold for a time to a student who is yearning for the title of doctor for the sum of fifty or sixty pounds. We know not how the provincial practitioners can be justly censured for the course which they have thought it their duty to pursue in obtaining their parochial office while not a word of blame is to be thrown out against the monopolising and hungry traffickers in disease and suffering in the great endowed hospitals of the nation.

But the attempt has now been fully made to secure the respectability as well as the pecuniary interests of the profession by rendering medical education expensive and never was there a more signal or self-evident failure displayed than has been exhibited in the effort which has been expended to carry into operation this fraudulent narrow minded irrational scheme.

From a *new* paragraph p. 234

The cerebral development of JAMES GREENACRE who was executed on Tuesday last for the murder of HANNAH BROWN was strictly confirmatory of the doctrine of phrenology.

From a letter on *The Ergot of Rye* Speed of its Operation p. 230

I am of opinion that contractions may and I think do take place in less than 15 minutes after the use of the seeds (cornutus). On referring to my case book I find notes of two cases wherein contractions came on in 12 minutes after the administration of the ergot and I also find a case published in THE LANCET of Sept. 20th 1827-8 by Mr J. C. Jerrard where the pains increased in 10 minutes after the exhibition of the ergot; but much depends on the quality of the ergot and the mode of preparing the decoction; if it be ground in a coffee-mill with a little lump sugar and boiled in a French pan I have found it more certain in its effect than when commonly produced in a mortar and boiled in an iron pan. I am Sir your obedient servant.

CHRISTOPHER BRADLEY M.B.C.S. & C.
Church near Blackburn Lancs. 4th April 1837

OBITUARY

ARCHIBALD DONALD, M D Edin, F R C P Lond,
F C O G

EMERITUS PROFESSOR OF CLINICAL OBSTETRICS AND GYNAECOLOGY
IN MANCHESTER UNIVERSITY

WE announced last week the death of the distinguished gynaecologist, Prof Archibald Donald, which occurred on April 18th at his house in Alderley Edge, Cheshire, in the 77th year of his age.

Archibald Donald, the son of Mr John Donald of Edinburgh, was born in 1860 and educated at Craigmount House School and the University of Edinburgh. He graduated as M.B., Ch.B. with honours in 1883, proceeding to the M.D. degree in 1886. He served

PROF DONALD

as house surgeon at the Royal Maternity Hospital, Edinburgh, and was then appointed resident obstetric surgeon at St Mary's Hospitals, Manchester. This was in 1885, and from that time forward to the end of his long career he worked in Manchester. After three years as a senior resident of St Mary's Hospitals he was elected to the honorary staff and was recognised at an early age as a leader in this branch of medicine. By this time he had produced a small but

valuable book on natural labour. In this introduction to the science of midwifery he disclaimed any intention of teaching the procedures needed in the presence of complications, but he defined and described the abnormalities which rendered further assistance desirable. The teaching was full and sound, and the book ran through eight editions. In 1895 Donald was elected gynaecological surgeon to the Manchester Royal Infirmary, and in 1912 professor of obstetrics and gynaecology in the University.

For those who have worked only under modern conditions it is difficult to visualise the circumstances in which a surgeon worked in 1888, the year Donald was appointed to the staff of St Mary's Hospitals, Manchester. It is true that the work of Lister was gradually permeating surgical work, but the methods were still, and for many years continued to be, those of antiseptics and included the carbolic spray and other methods, cumbersome, inefficient, and trying to operator and patient. There were no steam sterilisers for instruments, gown, and dressings, no gloves, no masks or caps, no electric light, no radiators, no Trendelenburg position, no reliable sutures. In these crude surroundings had worked the great pioneers of gynaecological surgery—Clay, Spencer Wells, Lawson Tait—and under these same disabilities began the work of Donald and his contemporaries who were to develop this branch of our profession into what we now know it.

Donald began his work with one great advantage over most of his contemporaries. St Mary's Hospitals provided one of the largest maternity centres in the country and being in the centre of a large industrial population in which rickets abounded it ministered to an enormous number of abnormal cases. Donald was the senior resident in this hospital for three years and was responsible each year for about 4000 births as well as acting as house surgeon to 40 gynaecological beds. It was a wonderful preparation for his life's work and gave him a practical clinical knowledge which few men of his age possessed.

Abdominal surgery was in its infancy and the number of patients who could be submitted to a major operation was necessarily restricted. This fact turned Donald's mind to the problem of prolapsus uteri, a disabling condition which abounded in a district employing so much female labour. Up to this time attempts had been made to improve the lot of these poor patients by the use of supports, by anterior colporrhaphy, by amputation of the cervix, or by repairing the perineum so that a pessary could be retained, but no one had devised any operation which could be considered a cure for this distressing state. Donald decided that the only likely way was a combination of these various procedures, and in spite of universal discouragement he made the attempt five times in 1888, in each case successfully. In his first two cases silver wire was the suture material, in both of these the wounds healed well and the women were able subsequently to return to their work as charwomen without any recurrence of their trouble. For this purpose silver wire had obvious disadvantages and Donald cast around for something more suitable. About this time he heard that some German surgeons were using catgut and he decided to try it as, being absorbable, it would be ideal for this type of operation if only it would hold sufficiently long to allow healing to take place. He used it in the remaining three cases in 1888 and was delighted with the result, especially as he could bury it and so build up the floor of the pelvis in layers, upon the technique of which a good colporrhaphy depends. The principle which he then evolved, of combining an anterior and posterior colporrhaphy with amputation of the cervix, making a strong pelvic floor and perineum by building up this tissue in layers with buried catgut, is still the method employed in one of the most successful operations in surgery—and from 1888 it has been continuously employed in his old hospital. The catgut first used by Donald in 1888 was imported from Germany—each hank in a small bottle of carbolic oil. This method of preparation was not wholly satisfactory and Donald experimented with many others and finally settled upon the one in which the catgut is soaked in alcohol and iodine. For a time he did try other suture materials but as his confidence in the preparation and strength of catgut increased he discarded these and during this century rarely used anything else. He must have been one of the first surgeons—if not the first—in this country to use it and he was certainly the first to rely entirely upon it. In the whole of his long career, at first using catgut ill prepared, he had only one case of tetanus.

In the realm of abdominal surgery Donald played a leading part, not so much in devising new operations as by perfecting and making workable the suggestions of others, his practical mind at once seizing upon the

casual and discarding the redundant. He was a brilliant operator with a long thin hand which could reach places inaccessible to more brawny colleagues. His hands were however always guided by his brain: he thought out beforehand what should be done and did it with delicacy, precision and speed and with complete confidence in himself. His inquiring and logical mind refused to accept views merely because they were ancient or had met with general acceptance. For long retroflexion of the uterus had been regarded as one of the common causes of female ill and if a uterus was found in this position it must be rectified and held in position by a pessary or operation. Donald could not accept this and pointed out on every possible occasion that the same symptoms occurred with anteverted as with retroflexed uteri and that many women with retroflexed uteri were symptomless. For long his was a voice crying in the wilderness and now that a more rational view is accepted his long fight may but should not be forgotten. He was a strong advocate of the curette: thus he did not use indiscriminately but only for specially selected cases and when he curetted he scraped the uterus quite clean. When a hysterectomy was necessary he believed in the clean sweep and removed both ovaries with the uterus. The conservation of an ovary on sentimental grounds made no appeal to him.

One of his outstanding features was his clinical memory which stood him in good stead in making a diagnosis in a difficult case. Generally he could recall a somewhat similar case and his skill in diagnosis was sometimes uncanny. Although best known as a gynaecologist, he was keenly interested in obstetrics and attended maternity cases up to the time of his retirement as he was a firm believer in the indivisibility of these two subjects. His earliest papers were on obstetrical subjects and just before his death he was writing about puerperal sepsis. He served upon the departmental committee of the Ministry of Health which reported upon the cause and prevention of puerperal sepsis and he held the view very strongly that efficient cleansing of the attendants would prevent most of these cases. At an early age he became the acknowledged leader in obstetrics and gynaecology in Manchester and the surrounding district and as time progressed his circle ever widened and he developed an enormous practice but even in his busiest years he found time to read occasional papers before the obstetrical section of the Royal Society of Medicine and he rarely missed a meeting of the North of England Obstetrical and Gynaecological Society where his ripe experience, clinical memory and humour made him one of the most popular speakers.

But first and foremost Donald was a clinician. A difficult diagnosis or a troublesome operation saw him at his best and ever the patient came first. The advances he made were in the clinical field and his writings were invariably on clinical subjects. Not that he despised the scientific side—far from it; he knew more pathology than he was usually credited with and was always interested in this branch and ready to apply any scientific fact. What irritated him was the pseudo scientific mind and the paper full of unproved theories based upon uncertain facts. Thus as a teacher Donald shone on the clinical side. For some years he was the professor of obstetrics and gynaecology at the Manchester University but systematic lectures full of theories and lists of names never appealed to him and he finally persuaded the University to bring his subject into line with medicine and surgery and to create a new chair of clinical

obstetrics and gynaecology. Here he was perfectly happy and at home, teaching by the bedside, recalling interesting cases from the vast storehouse of his memory, noticing signs unrecognised by others and finally proving at operation that his diagnosis was correct.

Prof Fletcher Shaw to whom we are indebted for much of the above gives the following personal picture.

Like all men of mark Donald had a strong character and he always had himself in perfect control. No matter how difficult or irritating the position he never betrayed what he felt by word or action. Always perfectly courteous he carried on outwardly quite cool and only those with intimate knowledge of him knew by the set of his jaw what he really felt. Slight in build and looking frail it was a wonder how he got through the vast amount of work which he did but he had a stronger constitution than he showed and he had the faculty of working without fuss or excitement. Upright, fearless and honest and entirely unself seeking he expressed his views openly though always with courtesy and with care not to hurt his opponent's feelings. He scorned the man who worked subterraneously or crookedly or pulled strings for his own glorification. What honours came his way—and they were many—gave him joy because they came unsought and generally from his own profession. He was generous and genial, radiating kindness and with a fund of quiet humour he loved his fellowmen and delighted to be with them as they with him. And as a colleague he was perfect. Kindly, courteous without jealousy, and ever ready to help he retained the friendship and respect of those he outstripped while in his juniors he inspired pride and devotion.

A surgical colleague at the Manchester Royal Infirmary also writes. To those who recall the extraordinary activities, physical and mental, alike of Archie Donald throughout a long and extremely distinguished professional career it must have caused considerable distress to witness the rapid decline of the last few months during which he was confined indoors, quite unable to enjoy his beautiful garden which he loved so well and on which he had expended so much thought, interest and energy. Of the details of such a career others, his colleagues in his special sphere of work are in a better position to testify than the writer but it is of Donald the man himself that one would pen a few words in most affectionate memory. Widely recognised from his early days as the outstanding exponent of his chosen specialty, Donald was throughout completely free from any taint of professional jealousy and his help was always most willingly and cheerfully given to his younger colleagues. Indeed, most of the honorary staffs of the M.R.I. and the St. Mary's Hospitals owe their position largely to his support since his influence with the governing bodies was greater than that of any other individual medical man and to have Donald on one's side practically connoted success in such elections. His modesty so far as concerned his own most valuable and original work was earned almost to the point of absurdity. Endowed with an almost unequal power of sifting the wheat from the chaff among the many suggestions of his medical friends of his day he was ever quick to pick up and to put into practice those ideas which seemed to him to be of real progress. A person of such calibre it is not surprising that he was at times intolerant of sham and every-dayness and although his

sought did not always coincide with the seeker's own inclinations yet in the long run it invariably proved correct. No one could be more loyal or generous as a friend. At the outbreak of the war Donald, then aged fifty-four, joined the *à la suite* staff of the 2nd General Western Hospital with the rank of captain, becoming thereby junior to most of those considerably junior to himself in civil practice, for some months, in addition to his other military duties, he took his turn to 'live in' and do what was, in reality, merely the work of a house surgeon—an admirable instance of his loyalty and devotion to what he thought to be his duty."

Prof Donald was at different times president of the obstetrical and gynaecological section of the Royal Society of Medicine, of the North of England Obstetrical and Gynaecological Society, of the Manchester Medical Society, and the Manchester Pathological Society. He was a LL.D. of the University of Edinburgh, and D.L. for the county of Lancashire. He married Maude, daughter of Mr R. B. Wilkinson, who survives him with two daughters and two sons. The home life was a very happy one, but they had cruel blows in the loss of two sons. The elder, an Oxford undergraduate, was killed early in the war at Gallipoli, and the third son, a barrister, died after a long illness. He is survived by a widow, two sons and two daughters, one of the sons being in medical practice in Manchester as a consulting physician.

SIR THOMAS YARR, KCMG, CB, FRCSI

WE regret to record the death of Major General Sir (Michael) Thomas Yarr, a distinguished officer in the R.A.M.C., and particularly well known for his excellent work in ophthalmology in connexion with military service. This occurred on April 24th in a London nursing home.

Thomas Yarr was the son of Thomas Yarr, J.P., of Rathgar, and was born at Cloughjordan, Tipperary. He was educated at the French College, Blackrock, and Mesnières. He went for his medical training to the school of the Royal College of Surgeons in Ireland, took the diplomas of L.R.C.P.I. and L.M. in 1882, and

almost immediately joined the R.A.M.C. He distinguished himself at Netley, gaining the Herbert prize, the Parkes medal, and the Martin and Montefiore memorial medals. He took the FRCSI diploma and was at first attached to the 1st Battalion of Coldstream Guards. From 1895 for the following four years he was seconded to serve under the Foreign Office as physician to the Crown Prince of Siam. At the expiration of this office he was appointed to the staff of the Governor of Bombay, a post which he held

for five years—i.e., until 1906, when he was promoted lieutenant colonel. Both in Siam and in Bombay Yarr made his mark by his quiet efficiency and broad

grasp of affairs, and while in Bombay his interest in ophthalmology developed, resulting in special work in connexion with diseases of the eye peculiar to the East. He now used his leave in attending continental clinics in Berlin, Paris, and Vienna, and held also the post of chief clinical assistant at the Royal London Ophthalmic Hospital. Major Yarr saw service in the South African War and was present at operations in the Orange Free State, Transvaal, and Cape Colony, receiving the Queen's medal with four clasps. His experiences there were drawn upon in his text-book, *A Manual of Military Ophthalmology*, which appeared in 1902. The book was directed particularly to the needs of medical officers of the Home, Indian, and Colonial Services, and in its plan it followed familiar lines, but because of their common occurrence in soldiers, particular stress was laid on the gonorrhoeal, syphilitic, and malarial infections in relation to diseases of the eye. Also he laid stress on the regulation in the Army Orders, which had just been issued, giving permission to both officers and men to wear spectacles. The regulation was due to the fact that in the South African War the bad sight of many combatants was held to have constituted a real drawback to certain operations. Particular attention was also paid by Yarr to injuries to the eye from gunshot wounds and the entrance of foreign bodies into the eye, a subject which he further dealt with in a paper communicated to the proceedings of the annual meeting of the British Medical Association in the same year.

At the outbreak of the European War Yarr served as A.D.M.S. and D.D.M.S. of the Mediterranean Expeditionary Force. He was present at the landing at Gallipoli, and later did distinguished service in Egypt and at Malta, where the hospital organisation was put to a heavy strain by the large number of cases brought to Valetta from every arm of the fighting services. Yarr was promoted temporary surgeon general in 1916, was mentioned in dispatches, received the C.B., and, in 1917, was promoted major general and appointed a KCMG. He was given also the Legion of Honour and became a Knight of Grace of the Order of St John. At the conclusion of hostilities he was selected to be Inspector General of Medical Services, a post which he held until 1921.

Major General Yarr was 75 years of age at the time of his death. He was unmarried.

THOMAS GUY MACAULAY HINE, OBE, M.D. Camb

Dr Macaulay Hine, who died on April 25th, aged 66, was the son of the late Mr George Hine, F.R.I.B.A., consulting architect to the Royal Commission in Lunacy, who built some twenty of our largest asylums including Claybury. Dr Hine was educated at Charterhouse and King's College, Cambridge, and went for his medical training to St Bartholomew's Hospital. He graduated as M.B. Camb in 1904 and became house physician to Sir Norman Moore.

Hine possessed a special flair for engineering, and in his youth he spent a year in Germany making a practical study of it. At Cambridge, however, he decided to study medicine, and after he had qualified and finished his house appointment settled down to study the fermentative characters of organisms of the diphtheria group. He wrote his M.D. thesis on the results of this investigation, which showed for the first time that certain carbohydrates, especially saccharose and dextrine, can have a useful application for the purpose of identifying the Klebs-Löffler

SIR THOMAS YARR

(Photograph by Russell)

for five years—i.e., until 1906, when he was promoted lieutenant colonel. Both in Siam and in Bombay Yarr made his mark by his quiet efficiency and broad

bacillus. When during the first winter of the war cerebro-spinal fever broke out among recruits then in training and a large epidemic was threatened special measures became necessary for checking its spread. The procedure adopted was under the direction of Sir William Horrocks assisted by the late Dr R. J. Reece and by Dr Mervyn Gordon. A central laboratory was set up at Millbank with a travelling laboratory attached to it. Dr Gordon gave practically the whole of his time to the research and as various points came to light they were applied by Dr Hine who acted as O.C. Central CSF Laboratory. Thus when a special medium was arrived at for detecting the meningococcus in the nasopharynx Dr Hine manufactured and distributed it on a large scale to military laboratories some fifty in number all over the country. Later on he undertook in the same way the preparation and distribution of monotypical agglutinating sera and suspensions wherewith to check them and managed to do a piece of research work as well on the optimum procedure for the purpose of preparing this serum. Later he undertook in the same way the distribution of special monotypical therapeutic serum and assessed its potency in a careful report. The special reports Nos. 3 and 60 on cerebro spinal fever of the Medical Research Council series contains several valuable contributions by him.

Towards the end of the war when some form of mass disinfection became desirable for diminishing the abundance of the meningococcus in the nasopharynx experiments at the Central Laboratory made on actual carriers showed that the comparatively delicate meningococcus can be temporarily got rid of by causing carriers to inhale steam laden air charged with droplets of zinc sulphate (1/50). Hine's previous training as an engineer now enabled him to devise a special jet for the purpose of keeping the air of an inhaling room charged with zinc sulphate droplets of the required strength and later the Navy adopted this device employing air compression instead of steam for the purpose of spraying. For his services during the war Hine received the O.B.E. and was given the honorary rank of Major. After the war he assisted the administrative staff of the Medical Research Council for a time, but for several years past he lived in retirement in Devonshire.

In 1918 he married Miss Margaret Lillywhite who survives him with two children a son aged 16 and a daughter. Dr Hine's sister Mrs Coxon is the well known novelist Muriel Hine. Dr Hine had been a past master of the Worshipful Company of Fruitcrs and was an enthusiastic fisherman and very popular in lay as well as medical circles where his genial presence will be much missed.

PARLIAMENTARY INTELLIGENCE

THE FACTORIES BILL IN COMMITTEE

THE Factories Bill was further considered by a Standing Committee of the House of Commons on April 20th. Major LLOYD GEORGE was in the chair.

The discussion was resumed on Clause 68 which provides among other things that subject to certain exceptions, the total number of hours worked by women and young persons in factories exclusive of intervals for meals and rest shall not exceed 9 in any day nor exceed 48 in any week; that the period of employment shall not exceed 11 hours in any day and shall not begin earlier than six o'clock in the morning nor end later than eight o'clock in the evening or on Saturday one o'clock in the afternoon; provided that where women or young persons are not employed on more than five days in the week the total hours worked may extend to 10 and the period of employment may extend to 12 hours, in any one day.

Mr A. SHORT moved an amendment to limit the hours of work of women in factories to 40 per week. At the suggestion of the chairman the Committee agreed to discuss at the same time two other amendments on the Order Paper proposing that the hours of work of young persons in factories should be limited to 7 per day and 40 per week. Mr Short said that up to now the Committee in the consideration of this clause had acted on the advice of the Home Secretary taken a most reactionary course. None of the amendments put forward by the Labour Party which were calculated to improve the position of employees which would come under this clause had been accepted. He would like to know whether the Home Secretary and the Home Office were in the pocket of the employers as to the provisions of this Bill. Women were more prone to accidents than men and now that workshops were being included under this Bill he had no doubt that there would be an increased number of accidents. They must make this Bill worthy of the occasion. Forty-eight hours work per week was too long for women. On the question of hours the employers of this country had been most reactionary and retrograde and it was for Parliament by legislation to force them to introduce a 40 hour week.

Mr GRAHAM WHITE said it was absolutely necessary for the well being of the country that young people should be fit both mentally and physically. The hours of work permitted under the Bill did not allow that degree of fitness to which the individual was entitled and which the nation required.

Mr MCCORQUODALE said he was particularly interested in young persons but he thought that having decided to reject the 40 hour week for men they must necessarily reject it for adult women. He thought that this country would be well advised to hold its hand in regard to the question of the 40 hour week until it had seen what would happen in France. According to his information at the present time the net result of the 40 hour week being put into practice in France had been to increase prices by nearly 30 per cent which meant that the working men and women in France were 30 per cent worse off than they were before as they got the same money wages. But the question of young persons—especially those under 16—was entirely different and he strongly urged the Government to meet them in that matter. He did not believe that young persons—especially those under 16—could work 48 hours a week and maintain the best of health.

Mr ELLIS SMITH said that he was concerned about the young people who went into industry fresh from school particularly those between the ages of 11 and 16. More and more in modern industry they found that young persons were being put on repetition work. Work was being speeded up in this way until the increase in production in Great Britain since 1920 was greater than in any other capitalist country in the world. In big factories employing repetition methods a new process was being carried out known as micromotion introduced from America. Persons were specially trained to watch people at work in the factories. Films were taken of the people at work and afterwards discussed by managers and assistants in order to decide what unnecessary use of human energy there had been and what unnecessary operations could be cut out. That was a good thing. It was important in these times to increase production and obtain the maximum output in the least number of hours possible but instead of being looked upon as a blessing methods of increased production were

regarded as a menace by the workpeople because they were not getting the benefits from this increased production which they ought to do.

Mr DENMAN said that he did not think they could confine the working hours to seven a day. He thought that the Committee ought to agree to limit the hours of young persons to 40 per week. Since the passing of the Education Act the Government had launched a great programme of physical development and a 40-hour week was the maximum which was consistent with the declared policy of the Government in those respects. The refusal of a 40-hour week for young persons would cause severe disappointment and cause a drift away from the support of the National Government.—Viscountess ASTON said that Mr Denman had made it almost impossible for the Government to reject the proposal for a 40-hour week for children.

Wing Commander WRIGHT said that as an employer with a factory, in which a good deal of repetition work was done, he was in entire agreement with almost everything that Mr Ellis Smith had said. There was no question that they could get the same sort of production in very much shorter hours and if they saw that their workpeople got a just reward for the extra effort they must make. He believed that a 40-hour week was in sight. In his own factory the workpeople always worked only 45 hours a week and they found that the workers were better, healthier, and happier, that they earned the same money, and that production had not decreased. He would like to see the hours of work of young children up to 16 reduced so far as to make it uneconomical to employ them for production in a factory while making the hours sufficient for them to be employed for instruction.

Sir J SIMON, Home Secretary, said that there were at present about 3,000,000 men employed as workpeople in manufacturing industries, about 1,500,000 women over 18, and something like 1,000,000 young persons under 18, and of that number over 500,000 were under 16. The supply of juvenile labour in this country would fall off in a very few years, and it was much better to deal with the matter deliberately now before trouble had been stored up. But it would be a very great mistake to regard the proposals of this Bill as though they did not represent a very great improvement in this respect. As far as the present law was concerned, from the point of view of permitted hours, juveniles between 14 and 16 and between 16 and 18 and women of any age were all treated, and were, on a level. The hours at present permitted for women and young persons classed together were 55½ in textile factories and 60 hours in other factories. He was glad to think that in most cases these very long hours were never touched. But at present there was an agreed working week—say of 48 hours—and on top of that there was a very large quantity of overtime which might extend over the whole year. In that respect women and young persons up to now had not been treated separately.

The first thing to notice about the present Bill was that it contained a gradation as regards hours. The question to decide was whether the gradation was steep enough. Under the Bill as at present drawn up adult men, as before, were left to collective bargaining and so on. There was a statutory limit of 48 hours a week for women with permissive overtime, which was limited both in number of hours and in number of weeks. As regards young persons between 16 and 18 there was a 48 hours week, but a more limited provision concerning overtime, and as regards young persons between 14 and 16 there could not be any overtime. The gradation was an entirely new and important principle. There came the question as to whether they could do better than was done in the Bill as regards juveniles between 14 and 16. He had for some time taken the view that they could. He would like to see the permitted hours of juveniles between 14 and 16 reduced. On inquiry the medical advisers to the Home Office

had advised him that the existing 48 hours could not be said, on present information, to be injurious to health, but, naturally, they would be very glad to see more time for leisure and recreation. He would put the case rather on the ground that whether they considered educational policy or physical recreation, or the future conditions under which young citizens were going to grow up, it was high time that they had a more limited number of working hours than 48 a week.

Mr GIBBINS. Do the Minister's medical advisers, in suggesting that it is not injurious to work 48 hours a week between 14 and 16 years of age, have regard to any consequences later for young persons who work those hours?—Sir E GRAHAM-LITTLE. Is the right hon. gentleman aware of the unanimous opinion expressed in the medical press on this subject?

Sir J SIMON said he had stated the opinion of his skilled advisers, but on general grounds he took it that it would be better if they could get the hours reduced. But first of all more information must be obtained as to what the hours ought to be, and therefore he suggested that the alteration should be made when the Bill reached the Report stage. He did not believe that it would be possible to introduce such a provision as early as other provisions in the Bill. There must be sufficient time for the important industries to consider the question of reorganisation, but they could possibly bring the improvement into force within two years. They must leave to a particular industry the opportunity of proving, if it could, that in each case a figure different from the statutory figure—it might not be as much as 48, it might be something between the two—was justified. His view was that before that could be done three things would have to be proved: first, that the hours in that branch of industry could not reasonably be regarded as injurious to the health of young people; secondly, it would be right to stipulate that the industry must prove that the hours were not only consistent with the health of the children, but that the organisation and proper carrying out of that industry made it desirable that the young people should work these longer hours side by side with their elders; and thirdly, the industry would have to prove that the juveniles would be engaged in work of such a character as would familiarise them with and help them to train for processes in which the older people were employed and would be likely to lead up to their employment in those processes. He was not saying that these exceptions would be taken advantage of, he did not know to what extent they might be necessary, but it seemed that they constituted a fair proposal to make to industry.

Mr SALT. Would the suggestion regarding health cut out all repetition work?—Viscountess ASTON. And would the exception with regard to children learning a trade be dependent on proof that they were really learning it?

Sir J SIMON said that that was his idea. He had not the least doubt that as a result of his statement the Home Office would receive a great deal of information before the Report stage of the Bill. He would be happy indeed if that information proved to be in support of an improvement of this sort.

Mr VIANI said that the Labour Opposition were grievously disappointed with the Home Secretary's statement.—Mr McCORQUODALE said he thought that the Home Secretary had met the Committee in a very frank and fair manner. The Committee adjourned.

The consideration of the Bill was resumed on April 22nd. The discussion on Clause 68 was continued.

Sir J SIMON, referring to his statement at the previous sitting, said that the modifications which he had sketched out and which he had suggested should come into force after an interval of two years would have to be expressed in a clause which provided that after that interval the figure 48 would be altered to a smaller figure with the other provisions that he indicated. That could properly be done in a

new clause which would be Clause 69. Clause 68 would be a provision as to what would happen when the Bill passed and the new Clause 69 would be a provision as to how that would be altered after an interval. After further reflection he had come to the conclusion that the proposed change could better be made in Committee than on the Report stage and he would undertake that that should be the procedure followed.

Mr WAKEFIELD urged that the Home Secretary should reconsider the position of the hours of work of young persons between the ages of 16 and 18 with a view to applying similar conditions to those which he had foreshadowed for young people between 14 and 16. It would be impossible to carry out the provisions of the Bill for physical training and recreation unless young persons worked shorter hours. The health of our young people was the greatest asset we possessed and it was important especially as the birth rate was now declining that we should make every effort to preserve it.

Viscountess ASTOR said it was just as important that hours should be reduced for children from 16 to 18 as for those between 14 and 16. This was a wonderful opportunity and if the Government did not take it it would make their grant for physical fitness absurd—Mr BROAD said he questioned the medical advice given to the Home Secretary to the effect that factory work had no effect on the health of children. Such work stunted them in mind and body. He hoped that they would be able to restrict the hours of employment of young people until the age of 21.

Sir E. GRAHAM LITTLE said that there were certain medical and educational arguments which had not been brought out quite explicitly and which made a very special class of the children from 14 to 16 years of age. It was for that class that he wanted very particularly to plead. Medical opinion was unanimous in wishing to restrict the hours of labour of children from 14 to 16 years of age. There was no division of opinion on that matter in any informal circle. He hoped that the Home Secretary would go beyond his official advisers in that respect. In the period from 14 to 16 years of age the whole structure of the child physical and psychological changed. A very great deal of work had been done—he was glad to say chiefly in this country—in investigating the psychology of that period. It was a very important consideration. The mental and physical stability of the child in those years was in a state of turmoil. The child from 14 to 16 years of age ought not to be in a factory at all. It was a most distressing thing that he should ever have been allowed to be there. Our descendants would think as harshly of us for having permitted it as we thought harshly of those persons who allowed children of tender years to work in a factory for 20 hours a day. The medical point of view was important but they pleaded also for the educational point of view. The spirit of enthusiasm, training, discipline and forward looking was what the children lost if they went into a factory. They did not want the children to lose it. Children who go on from 14 to 16 should be allowed to complete that part of their education, adding to the structure of theory and science and fitting themselves to become really skilled workers in trades and occupations. The work which they did in factories from 14 to 16 was in no way a preparation for a trade. They lost all the incentive which they learned at school and they had a great period of indolence as regarded mental activity because of the absence of any incentive. At 18 they were lifeless persons and were thrown again on to the labour market. That process was utterly uneconomic and foolish. They would be contributing to the making of a C3 nation if they did not make a great effort the opportunity for which was presented itself for physical reconstitution.

After further discussion the Committee divided on a Labour amendment limiting the working week for women and young persons to 10 hours. This was negatived by 21 votes to 15.

Mr LLOYD Under Secretary Home Office moved an amendment substituting 7 o'clock for 6 o'clock as the hour for beginning work in factories. He said that the Government were prepared to agree that work should not begin before 7 o'clock except in special cases where authorized by the Secretary of State. Under a new clause which would be moved later the Secretary of State would be empowered to allow the period of employment to begin earlier than 7 o'clock but not earlier than 6 o'clock in the case of a particular class of factory where the exigencies of the trade or the convenience of the persons employed so required.

The amendment was agreed to.

Mr SILKIN moved an amendment providing that the period of employment should end not later than 6 o'clock instead of 8 o'clock.

Mr LLOYD said that in certain circumstances it was for the convenience of the workers that they should start late. It would be impracticable as a matter of administration to fix an earlier period and then to give a large number of exemptions.

After further discussion Mr Lloyd said that he had been impressed with the arguments put forward and he asked the Committee to allow the Home Office to reconsider this matter from the point of view of young persons. The amendment was withdrawn.

Subsection (e) of Clause 68 provides that a woman or young person shall not be employed continuously for a spell of more than 4½ hours without an interval of at least half an hour for a meal or rest, so however that where an interval of not less than 10 minutes is allowed in the course of a spell the spell may be increased to 5 hours.

Mr WHITE moved to leave out the words "or young person" from the subsection. He said that it was not the intention of the amendment merely to take young people out of the protection of the clause. The amendment had to be read in conjunction with another providing for the limitation of spells of work of young people to 3½ hours.

Mr LLOYD said that the provisions in the Bill had been put in as a result of the experience of the Factory Department of the Home Office in order to provide the intervals and rest pauses that were necessary but also to avoid making unnecessary long rest pauses which were inconvenient and much resented by the workers concerned. He thought they ought to have heard some stronger reasons for the insertion of the amendment. These proposals had been incorporated in the Bill as a result of work subsidised by the Medical Research Council. Mr WHITE said that 4½ hours work at a time was a sufficiently long period for any young person who came straight from school. The amendment was negatived.

Sir E. GRAHAM LITTLE moved to leave out the words "four and a half" and to insert the word "three" in the subsection. He said that it was well established that spells of work of more than three hours especially in the case of young people caused attention to flag and the incidence of accidents was very largely due to and increased by inattention. Practical proof of that was to be found in statistics.

Mr LLOYD said that the hon. Member had put forward medical opinion that the proposal in the Bill was too long and that three hours was the maximum that ought to prevail. That was not the conclusion to which the Industrial Health Research Board came when they made a special investigation into these subjects. Their general conclusion after an examination of sickness records and so on was that it was impossible to obtain reliable evidence as to the change in the duration of work up to affecting sickness rates. Therefore in this matter medical opinion was divided.

Sir E. GRAHAM LITTLE: Does sickness rate include accidents?—Mr LLOYD: No, but from the accidents point of view the reports of the factory inspectors tend to show that it is not at the end of the period of work even in regard to young persons.

that accidents mostly occur. They tend much more to occur somewhere about the beginning of work or during periods of maximum production when there is a tendency to work too fast.

The amendment was negatived.

The further consideration of the Bill was adjourned.

GOVERNMENT AND MILK POLICY

NEW BILL PROMISED

In the House of Lords on April 27th, on the motion of Lord MARKS, the Poole Corporation Bill was read a second time.

Lord CRANWORTH moved an instruction to the Committee which will consider the Bill to delete Clause 21, which relates to by-laws "as to pasteurisation, &c., of milk." He said that the Poole Corporation admitted that this clause was included in the Bill because of the recent outbreak of typhoid at Bournemouth. This was panic legislation.

Viscount HALIFAX, Lord Privy Seal, said that the health of the people must be the first and last consideration, and the question of vested interests did not arise. The Bill was not opposed on petitions, but he understood it was the intention of the Chairman of Committees to refer the Bill to a Select Committee of the House in order that the proposals as to pasteurisation might be examined. In the view of the Government such an inquiry would be unsatisfactory and probably inconclusive. An inquiry of that kind ought not to be held in connexion with any particular locality, the question could only be considered as a general one affecting the country as a whole. The Government had reviewed the whole matter, and he was authorised to announce that it was their intention to bring forward long-term legislation dealing with milk policy generally in the near future. In this connexion the Government would examine the question of pasteurisation in the light of all the evidence that was available with a view to deciding whether or not it would be in the public interest, with due regard to the interests of the milk industry, to include provisions with regard to it in the legislative proposals. He supported Lord Cranworth's motion.

Viscount DAWSON OF PENN said that the Poole experiment would have been a very valuable one, but they were obliged to be influenced by the question of cost. If it was to be such a costly matter he could see the force of the argument for waiting for a general measure. But no indication had been given how long it would be before that general measure came into operation. There was an overwhelming body of evidence in every civilised country that pasteurisation was an efficient means of preventing the continuance of certain infectious diseases. The mortality from tuberculosis had declined, but there had not been so much improvement in regard to the bovine type of infection as in regard to the human form of infection.

Lord Cranworth's motion was carried.

NOTES ON CURRENT TOPICS

In the House of Lords on April 22nd the Hydrogen Cyanide (Fumigation) Bill passed through Committee.

The Lords amendments to the Education (Deaf Children) Bill were agreed to in the House of Commons on April 21st. On April 22nd, in the House of Commons, the Special Areas (Amendment) Bill passed through Committee.

In the House of Lords on April 27th the Special Areas Bill, which was read the third time in the House of Commons on April 26th, was read a first time.

In the House of Lords on April 27th Lord STRATHCONA AND MOUNT ROYAL moved the second reading of the Maternity Services (Scotland) Bill.

The Bill was read a second time.

The Edinburgh Royal Maternity and Simpson Memorial Hospital Order Confirmation Bill was read the third time in the House of Commons on April 26th.

Consideration of the Widows', Orphans', and Old Age Contributory Pensions (Voluntary Contributors) Bill was concluded by the Standing Committee of the House of Commons on April 27th. Sir KINGSLEY WOOD, Minister of Health, announced that on the third reading in the House of Commons he would make a statement with regard to the date of the coming into operation of the scheme. The Bill was ordered to be reported, with amendments, to the House of Commons.

QUESTION TIME

WEDNESDAY, APRIL 21ST

Medical Reports on Gaol Conditions in Kenya

Mr DAY asked the Secretary of State for the Colonies whether he would give particulars of any recent reports on gaol conditions that he had received from the local medical authorities in Nairobi, Kenya, and the number of deaths from tuberculosis that had been recorded at the Nairobi prison for each of the last three years, and what steps it was proposed to take to further improve existing conditions.—Mr ORMSBY GORE replied: I have received no reports from the medical authorities in Kenya relating specifically to gaol conditions in the Colony. The annual reports of the Prisons Department for the years 1933, 1934, and 1935 indicate that the total deaths in the Nairobi prison during those years were 12, 31, and 22 respectively, of which more than half were due to pneumonia. No deaths were due to tuberculosis. A separate ward for the hospital treatment of patients with this disease was constructed in 1933.

Mr DAY: Does the report show that the conditions in this gaol are considerably worse than they are in other Colonial prisons?—Mr ORMSBY GORE: No, Sir.

Hillingdon Hospital and Omnibus Services

Mr DAY asked the Minister of Transport whether he was aware that there was no omnibus service from the terminus at Hillingdon Church to the Hillingdon County Hospital, Middlesex, which necessitated out-patients attending this hospital daily walking long distances, and caused many of them to rest by the wayside or collapse on arrival at the hospital, and if he would make representations to the omnibus authorities serving this district asking them to continue the omnibus service to this hospital during certain hours.—Mr HORE BELISHA replied: The Board have informed the councils concerned that they are prepared to make application for a route between Uxbridge and West Drayton passing the hospital as soon as the roads are suitable for omnibus operation.

THURSDAY, APRIL 22ND

Irish Casual Labour and Insurance Payments

Captain McEWEN asked the Minister of Labour whether he was aware that in the case of casual labour from the Irish Free State contributions to the national health and unemployment insurance funds were demanded from employers, and, seeing that in most cases the labourer did not remain in this country for as long as the statutory six months which would enable him to qualify for benefit, would he take steps to alter this position.—Mr ERNEST BROWN replied: Under the general scheme of unemployment insurance joint contributions are payable in respect of all persons employed in insurable employment in Great Britain. Under the agricultural scheme persons not domiciled in and ordinarily resident outside the United Kingdom are excluded from unemployment insurance. Their employers are, however, required to pay employers' contributions in order to avoid a special inducement to employ such persons. In the case of health and pensions insurance, there is an arrangement whereby contributions paid in respect of employment in Great Britain count for benefit in the Irish Free State.

Coroners and Post-mortem Examinations

Mr WILSON asked the Home Secretary whether he could state for the last available year and for other than county boroughs the number of post-mortem examinations directed or requested by coroners and in how many of these cases the examination took place in hospitals, in

mortuary premises and in other places respectively—Sir JOHN SIMON replied. Excluding the City of London, the County of London and county boroughs forming complete coroners' districts the figure for 1936 was 10,274. I have no information which would enable me to answer the second part of the question.

Mr WILSON: Is the right hon. gentleman aware that on a recent occasion there was no fit place for a post mortem examination and that it was held on the village green—Sir J. SIMON: I do not know that.

Magistrates and the Birching of Boys

Mr SHORT asked the Home Secretary if he was aware that nine boys were ordered to be birched by justices in the West Riding juvenile court, Doncaster, on April 7th, whether the sentences had been carried out and whether seeing that a committee was being appointed to consider the question of birching he proposed to advise magistrates and others not to order birching between now and the committee reporting—Sir JOHN SIMON replied. Yes, Sir, nine boys were ordered on April 7th to receive three strokes of the birch. Eight were birched on that day, a medical officer certified that the ninth was unfit for the punishment. As it must be widely known that I have decided to appoint a committee to consider the question I do not think that further action on my part is required.

Mr SHORT: Will the right hon. gentleman go a little further than that and advise magistrates not to order such sentences having regard to the fact that a committee of inquiry is being appointed?—Sir J. SIMON: I do not think I can do that. The duty of the committee will be to ascertain and to advise and I am hurrying up the appointment of the committee in every possible way. In the meantime I am sure that benches of magistrates will realise that I regard this subject as one which needs investigation.

Deaths in Armley Gaol, Leeds

Mr LOWN asked the Home Secretary whether he would make a statement concerning the death of one man two days after admission to Armley Gaol, Leeds, as a debtor and another, 19 years of age, who had committed suicide in the gaol during this month and if he would institute an inquiry into the circumstances—Sir JOHN SIMON replied: I have already made careful inquiry into both these cases. The first prisoner was a man of 43 who was received into Leeds prison on April 2nd. He was examined on admission by the medical officer and found to be suffering from valvular disease of the heart. In view of this it was arranged that he should be given no work requiring physical exertion. On the night of April 3rd he died—apparently in his sleep. The law requires that there shall be an inquest on every death in prison and the jury found that death was due to natural causes. There is no suggestion that anything in his treatment in prison contributed to his death, and there is nothing the prison staff could have done to prevent or to render less likely this sudden heart failure. The second case was that of a young man serving a sentence of three months in the second division. He was examined on his admission on April 2nd and there was nothing wrong with him physically or mentally. His conduct while in prison was good; he gave no trouble and there was no question of any disciplinary treatment. On April 12th he was at work in the morning in association with other prisoners and there was nothing abnormal in his behaviour. At about 1.45 he was in his cell and was seen by the medical officer in the course of a routine round of the cells. He was then quite cheerful. At 1.15 the librarian officer who distributes books to prisoners visited his cell and the prisoner was then sitting reading. At 1.40 he was found dead, having hanged himself from the window bars of his cell. In this case also there was an inquest. There was nothing the prison staff could have done to prevent this tragic occurrence and there is no suggestion that there was anything in the nature of harsh treatment which might have contributed to this impulsive suicide.

Mr LOWN: Is the right hon. gentleman aware that there is some uneasiness in Leeds about these two tragic events and will the Home Office not call for some further inquiry into this matter as well as other matters in

connexion with our prisons so as to remove the possibility of such happenings as these?—Sir J. SIMON: I am not at all surprised that people in Leeds or elsewhere should feel anxious about these incidents and they are deeply distressing. I need not say that to the Home Office but I have given information quite impartially and I hope very much that with the hon. Member's help that will allay public anxiety about these two cases.

Provision of School Canteens

Viscountess ASTON asked the President of the Board of Education whether in view of the growing realisation of the importance of nutrition and particularly of the fact that children who underwent physical exercises should be properly fed, he would take measures to ensure that no new school, whether for juniors or seniors, was built without provision being made for a canteen—Mr OLIVER STANLEY replied: I have already drawn the attention of local authorities to the desirability of providing school canteens at schools where children come from a distance and in the consideration of plans for new senior schools this point is always borne in mind. I am also prepared to consider any proposals by local authorities to make arrangements for school dinners in schools where children do not come from a distance but I am not prepared to require the provision of canteens in all new senior and junior schools.

Anthropometric Surveys of School-children

Mr EDE asked the President of the Board of Education if he would publish the results of the anthropometric survey made by his officers of the children attending the Alderman Wraith Secondary School, Spennymoor County Durham, the Sarbston County School for Boys, Surrey, and the Woking County School for Girls, Surrey—Mr OLIVER STANLEY replied: I do not think that the subject is one of sufficient general interest to justify separate publication of the particulars but I am having a copy placed in the Library of the House for hon. Members who may be interested. Moreover I understand that the Board's chief medical officer proposes to refer to the matter in his next annual report.

Mortuaries

Mr WILSON asked the Minister of Health how many local authorities other than those of county boroughs had provided mortuaries as empowered by Section 143 of the Public Health Act of 1875; and how many had not made any such provision—Sir HENRY WOOD replied: I have no complete information on this subject but since April 1st 1920 loans have been sanctioned by my department for the provision of mortuaries by 63 local authorities other than county boroughs.

Maternal Mortality Reports

Mrs TATE asked the Minister of Health when the report on the special investigations into maternal mortality made by his officers in various parts of the country would be available—Sir HENRY WOOD replied: I hope to lay this report before the House in the course of the next few days.

Infantile Mortality

Mr THORNE: Has the Minister any reasons why there is such a very low infantile mortality in Letchworth?—Sir K. WOOD: Letchworth is a very small unit, the total births being about 700 or less each year. During the past few years the infantile mortality rate has been 1.62 per 1,000 live births.

Mr THORNE asked the Minister of Health the rate of infant mortality in the city of Letchworth and if he can say what is the average infantile mortality for England, Wales, and Scotland—Sir HENRY WOOD replied: For 1935 the last year for which separate figures are yet available the mortality rates of infants under one year of age per thousand live births were: Letchworth, U.D. 1.62; England, 36; Wales (including Monmouth), 63. With regard to Scotland the hon. Member should address an inquiry to my right hon. friend the Secretary of State.

Hospital Facilities in Newfoundland

Mr BROOKE asked the Secretary of State for Dominion Affairs whether any steps were being taken to remedy the lack of hospital facilities in Newfoundland which was shown in the report of the Department of Health and Welfare, and whether any measures are contemplated to combat the high rate of infant mortality and the prevalence of tuberculosis—Lord HARTINGTON, Parliamentary Secretary for Dominion Office, replied The measures now in progress for the improvement of the hospital facilities in Newfoundland, including the enlargement of certain hospitals at St John's and the completion of a chain of Cottage Hospitals outside the capital, were summarised in chapter iv of the annual report of the Commission of Government for 1936, Cmd 5425 My right hon friend has recently received from the Governor detailed proposals for the extension of the Tuberculosis Sanatorium, and a special survey of tuberculosis conditions is in progress Consideration is also being given to the establishment in outpost districts of prenatal clinics and child welfare services corresponding to those in operation at St John's I may add that special attention will be given to the improvement of medical and health facilities in the formulation of the long term programme of economic reconstruction which is now under consideration

Mr PETHERICK Is it not the case that a considerable number of additional medical officers have been appointed?—No further answer was given

MONDAY, APRIL 26TH

Medical Practitioners and Health Insurance

Mr RHYE DAVIES asked the Minister of Health whether he was now able to state the terms of reference and the personnel of the tribunal to inquire into the fees paid to panel doctors under the national health insurance scheme—Mr HUDSON, Parliamentary Secretary to the Ministry of Health, replied No, Sir The arrangements for the inquiry are not quite complete, but I will inform the hon Member as soon as they are settled

TUESDAY, APRIL 27TH

The Army and Blood Transfusions

Mr WAKEFIELD asked the Secretary of State for War what supplies, if any, were available of human blood suitable for transfusion, grouped and bacteriologically tested, for large-scale emergency treatment—Mr DUFF COOPER replied The Army policy is not to store blood for large-scale transfusion, as the period for which this can be done is very limited Each military formation has a number of donors grouped and tested who are available for this service

Mr WAKEFIELD asked if the right hon gentleman was aware that in Russia large stores of human blood were available and had been used very successfully in cases of emergency—Mr DUFF COOPER said that there were reports to that effect, but it was more satisfactory to store our blood in our people—Mr MUFF May I ask if it is blue blood?

The Causes of Silicosis

Mr TOM SMITH asked the Secretary for Mines if he had any information concerning discussions relative to silicosis and its causes mentioned recently by the President of the Institute of Mining and Metallurgy—Captain CROOK SHANK replied I have not yet seen a full report of the President's speech last Thursday, but I understand that it referred particularly to the progress of research into methods of collecting samples of dust from the air breathed by mineworkers, and of examining and analysing such samples My Department is closely in touch with this work through its technical officers

Family Incomes and the Means Test

Mr OLIVER asked the Minister of Labour whether his attention had been drawn to the hardships caused by the inclusion, for the purpose of calculating family incomes in respect of the means test, of lump sums paid to injured workmen by way of compensation under the Workmen's

Compensation Act, and whether, in view of the fact that these commuted sums represented the loss of earning capacity, both present and future, of injured workmen, and were not savings or interest on investments, he would consider discontinuing assessing these settlements for the purposes of relief of unemployment existing in the households of these workmen—Lieut Colonel MUIRHEAD replied I would remind the hon Member that the special nature of these lump sum payments has already been recognised by the Board so that one half is treated as required for the special needs or personal requirements of the holder If the holder is other than the applicant or the applicant's husband, wife, father, or mother, the balance is taken into account only in so far as the actual income derived from it, together with any other available resources, exceeds the amount of the scale rates of the holder and his dependants In other cases the balance of one half is regarded as producing an income of 1s per week for each £25 in excess of the first £25

Day and Night Nursery at Bristol

Mrs TATE asked the Minister of Health (1) whether the Bristol Council proposed that one member of the staff of the Bristol day and night nursery in Ashley road, Bristol, should be a trained nurse, (2) what steps the Bristol Council were taking to ensure that fuller medical records should be kept at the Bristol day and night nursery, and (3) whether arrangements had now been made by the Bristol Council for systematic medical inspection of children in the Bristol day and night nursery—Sir J BLUNDELL, Lord of the Treasury, replied My right hon friend is in communication with the Bristol City Council regarding the three matters referred to and will inform my hon friend of the result

School children and Tuberculosis

Mr GROVES asked the Minister of Health how many cases of tuberculosis had been notified among school children during the last year for which the figures were available, in Chesterfield and in Sheffield, respectively—Sir KINGSLEY WOOD replied 394 fresh cases of tuberculosis were notified among children between the ages of 5 and 15 in Sheffield in 1936, and 7 were notified among children between the same ages in Chesterfield in 1935, the last year for which figures are at present available for that borough

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED
APRIL 17TH, 1937

Notifications—The following cases of infectious disease were notified during the week Small pox, 0, scarlet fever, 1678, diphtheria, 1019, enteric fever, 25, pneumonia (primary or influenzal), 1150, puerperal fever, 33, puerperal pyrexia, 137, cerebro spinal fever, 24, acute poliomyelitis, 8, acute polio encephalitis, 0, encephalitis lethargica, 0, dysentery, 18, ophthalmia neonatorum, 106 No case of cholera, plague, or typhus fever was notified during the week

The number of cases in the Infectious Hospitals of the London County Council on April 23rd was 3196 which included Scarlet fever, 853 diphtheria, 904 measles 39 whooping-cough 512 puerperal fever, 18 mothers (plus 14 babies) encephalitis lethargica 284 poliomyelitis, 1 At St Margaret's Hospital there were 19 babies (plus 5 mothers) with ophthalmia neonatorum

Deaths—In 123 great towns, including London, there was no death from small-pox or from enteric fever, 13 (0) from measles, 3 (0) from scarlet fever, 24 (5) from whooping-cough, 20 (3) from diphtheria, 53 (14) from diarrhoea and enteritis under two years, and 73 (10) from influenza The figures in parentheses are those for London itself

Greater London had one death from enteric fever Eight deaths from measles were reported from Birmingham and 4 deaths from whooping-cough from Manchester There were also 3 deaths from diphtheria at Birmingham

The number of stillbirths notified during the week was 299 (corresponding to a rate of 42 per 1000 total births), including 46 in London

MEDICAL NEWS

University of Oxford

The electors to the Nuffield professorship of obstetrics and gynaecology at Oxford announce the appointment of John Chassem Moir to the post, duties to start on Oct. 1st.

Dr Moir is 37 years of age and was educated at Montrose Academy and Edinburgh University. He graduated in 1932, and in 1938 gained the M.D. degree, his thesis on an obstetrical subject being awarded a gold medal. He is a fellow of the Royal College of Surgeons of Edinburgh and a fellow of the Royal College of Obstetricians and Gynaecologists. After some years' experience of general practice and of general surgery Dr Moir devoted himself to gynaecology and obstetrics. He studied in Vienna and Berlin and later having been awarded a Rockefeller travelling fellowship) in Johns Hopkins Hospital Baltimore, where he held the position of senior research assistant to the obstetrical unit at University College Hospital, London and, in 1935 was appointed reader in obstetrics and gynaecology in the University of London holding office at the new British Postgraduate Medical School. His most known research activity is the human pregnant and non pregnant uterine. This worked to the discovery of a new active principle in ergot and in a later combined investigation with the late Mr W. Dunder M.D. the substance responsible for the active principle was isolated and identified as a previously unknown α -ergometrine.

University of Cambridge

On Monday May 10th at 5 p.m. Prof A V Hill F.R.S will deliver the Linacre lecture. His subject will be the heat production of muscle and nerve.

University of Glasgow

On April 24th the following degrees were conferred—
 M.D.—Annie R. Chalmers, D. K. M. Chalmers, Edgar
 Cochrane J. A. M. Hall D. W. Hender and William Tellor
 (with commendation) B. M. Laird J. E. McNair
 In absentia

M.D. (A.B.) — D. Wright (with honours). I.C. Wilson
 (with commendation). M.O. Alakia. I.A.M. Beaton William
 Begg. S.A. Bond. J.M. Brown Robert Browning Bernard
 Camber. Annie Cameron. D.A. Cannon. Harold Crampton
 J.C. Curran. G.W. Davidson. W.G. Egan. R. Williams
 J.M. Guthrie A.L. Dick Alexander Donald, Marjole Frew.
 O.H. George. W.F. Gilford. A.M. Gilchrist. P.R. Goerl
 M.P. Graham. H.F. Gray. C.A. Hamilton. J.E. Harvie
 D.J. Hart. C. Howie. J.B. Hurll. Alexander Ja.k
 M.I. Kriesher. O.I.D. Lavan. J.C. Little. R.D. Ling John
 Ludlow. J.M. McBride. A.R. McDougall. O. Macintosh
 D.A. McEachern. W. Miller. W. Milne.
 D.N.B. Morrison Kenneth Murray. W. Oman. J.R. Proctor
 A. Rodger. D.C. Russell Joseph Shapiro. Bernard Smith
 N. Strirling. Idd. Stoll Irwin. A. Thomson. J. Timan
 J. Tuck. J. Walker. J. Watt. J. Q. Watson

Royal Faculty of Physicians and Surgeons of
Glasgow

At a meeting of the Faculty held on April 5th with Prof Archibald Young the president in the chair the following were admitted to the fellowship:—

Andrew Girdwood Ferguson and Thomas Ian Hay Gordon
(Glasgow) Donald Valter Marshall (Hull) and Arthur MacLennan
Duthie (Glasgow)

British College of Obstetricians and Gynaecologists

A meeting of the council of the College was held on April 24th with Sir Ewen Maclean the president in the chair. The following were formally admitted to the fellowship:—

(C) Rev. Thos. David Well Brownie (Dunblin) James Robertson
 Campbell, Canons (Cambridge), Robert Henry Joseph Mulhall
 Corbett (Dunblin) *Thoma Frederick Cockill (Wellington)
 New Zealand Herculano Diogo de Sa (Bombay), Charlotte
 Anne Douglas (Edinburgh) Henry Harvey Evans (Newra the
 Upper Tyne) Arthur Oliver Gray (London) Sidney Blash
 H. J. H. (London) H. J. H. (London) (Dunblin) (Dunblin) Andrew
 George MacLellan and William McKim Herbert MacLellan
 (London) George Henry Mahony (Patna) Perry Malpas
 (Liverpool) Maugenda Mehta (Bombay), Douglas Miller
 (Edinburgh) Cyril MacDonald Plimpton (Madras) and Frederick
 Leitch Leitch (London) and Leslie Serpell (London) and
 Leslie Serpell (London) John L. Plimpton (Sheffield) and
 Brian Herbert Swift (A. Ireland)

[illegible]

At the annual general meeting which followed Dr J P Hedley, Prof F E Murray, Prof Gilbert Strachan, Prof

William Gough and Dr D G Madill were elected to the council as representatives of the fellows and Dr J W G H Riddell Mr John Sturrock, and Dr A. W Spain as representatives of the members.

King's College Hospital

The Listerian Society of this hospital will meet there on Wednesday May 5th at 8 15 P.M. when Prof Charles Singer will speak on medicine in early England.

London School of Hygiene and Tropical Medicine

One Fishmongers' Company studentship is awarded annually at the school. It carries remission of fees for the DPH course. Applications to compete for the studentship must be sent to the secretary of the school, Keppel-street WC1 by June 14th. The examination will be held on June 22nd and 23rd.

Glasgow University Club London

This club will dine at the Trocadero Restaurant London W on Friday 28th May at 7.30 p.m. when the principal of the University Sir Hector Hetherington will be in the chair. The Earl of Derby will be the guest of the chair man. The hon. secretaries may be addressed at 62, Harley house London N.W.1

College of Physicians and Surgeons of Bombay

At a meeting held in January the council of the college decided to institute an examination for a diploma in ophthalmic medicine and surgery and appointed a committee to draw up regulations and a syllabus. On March 12th the report of this committee was adopted and the first examination for the diploma will be held in July. Copies of the regulations may be had from the secretary of the college.

The Factories Bill

The Council of the Save the Children Fund while welcoming the Factories Bill now before Parliament has passed a resolution urging its amendment so as to ensure that no child shall be employed in a factory before the age of 15; that no child or young person shall be permitted to work more than 40 hours a week; that no overtime be permitted for workers under 18 years of age; that holidays with pay be assured to all children and young persons; that the hour of leaving work may be sufficiently early to enable children and young persons to take advantage of available opportunities for education and recreation; and that the clause providing that the Home Secretary may suspend Part II of the Bill (dealing with safety) until 1910 be eliminated.

London County Council

A meeting of the Council on April 27th received proposals for a new antitoxin establishment at a site which is available at Queen Mary's Hospital, Carmichael. The accommodation at the existing antitoxin establishment at Belmont Station is still inadequate despite the alterations and additions which have been carried out from time to time and twice the existing space is required. The proposed new establishment which will cost about £116,000 will ensure a constant and ample supply for the Council's hospitals of products which are made at Belmont and also of others which are now being purchased. There will also be extra facilities for research work. The laboratory at Belmont will be retained for work which can conveniently be carried out there.

Other Improvements which are to be carried out at the Council's hospitals include the construction of two new isolation blocks each containing 60 single bed wards at the Southern Hospital. A new nurses home will also be provided and the existing accommodation for the nursing staff will be altered. The total estimated cost of these extensions is about £61,300. A new sanitary annex is to be provided at St George in the East Hospital and the sanitary annexes at Archway Hospital are to be remodelled and extended. A new operating theatre is to be added at St. Charles Hospital at a cost of about £2,000.

Dame Janet Campbell has been appointed a member of the hospitals and medical services committee of the Council.

Schorstein Research Fellowship in Medical Science, 1937

The Board of the Faculty of Medicine at Oxford will make an election to the above Fellowship in June, 1937, if a candidate of sufficient merit presents himself. The fellowship, which will be of the value of £300, will be tenable for one year from Oct. 1st, 1937, in any medical department or institute at Oxford, under such regulations as the Board may approve. Candidates must be graduate members of the University, holding a registrable medical qualification, and must be under thirty-five years of age on Oct. 1st, 1937. Candidates must submit their applications to the dean of the medical school, University Museum, not later than Monday, May 3rd, 1937. Each candidate must submit (1) evidence of age, (2) testimonials (three copies) or names of referees, (3) a statement of his career, (4) a statement of the department of medical science in which he proposes to research.

The British Social Hygiene Council

There is a real need for further subscriptions to the British Social Hygiene Council if its valuable work is to be continued in its present practical way. The B.B.C. will consequently afford the Council an opportunity of making a public appeal. This will be done on Sunday, May 2nd at 8.45 P.M., Prof. John Hilton making the appeal. In a second direction the Council is seeking public support by holding an Empire Ball on July 6th. The Ball will take place at Grosvenor House and an important number of patrons have already been secured. There will be a cabaret and various competitions for prizes, the tickets for the Ball are £2 2s each, or £10 10s for six, and it is hoped that visitors from overseas will support the entertainment. The tickets are obtainable from Grosvenor House, Park Lane, The Ball Committee, Carteret House, Carteret Street, Westminster, S.W.1, and the Over Seas League, Park Place, St. James's, S.W.1.

Incorporated Society of Chiropodists

The annual dinner was held at the Trocadero, London, on April 24th. The toast of the medical profession was proposed by Mr. Charles Doughty, K.C. Sir Frederick Menzies, F.R.C.P., in response, said that medical science was developing more and more in the direction of team work, one of the remarkable developments was the formation of groups of non-medical workers, without whom the efficient work of a hospital could not be done, radio-graphers, dieticians, electric therapists, masseurs, and so on. One of these days the work in which chiropodists were engaged must also become an essential unit of any hospital service. Thousands of people were going about the country suffering acutely from conditions of the feet which could be remedied by chiropodists who had an enormous sphere of work. So long as the members of the Incorporated Society of Chiropodists rigidly adhered to the high standards they had set themselves, they were bound to succeed in their aims. He looked to the greatest possible co-operation between them and the medical profession in the interests of the community. Mr. A. Simpson Smith, F.R.C.S., proposed the toast of "this most progressive society." Chiropody, he said, was assuming greater importance year by year and had long eclipsed the mere cure of the corn. Chiropody was rapidly becoming of national importance, particularly as every week something like 135 people were killed and 5000 injured on the road largely through not being quick enough on their feet. He foresaw that in the national scheme of physical fitness, that is about to be launched, there would be proper provision for the many C3 feet which were the increasing outcome of arduous occupations in industry. One could not have an A1 nation with C3 feet. Mr. John H. Hanby, F.I.S.Ch., responded from the chair. They had, he said, recently secured the co-operation of the Royal College of Surgeons with regard to their examinations and had every hope that the Royal College of Physicians would co-operate in a similar manner by confirming a recommendation made by a joint committee of both colleges thus strengthening the confidence which had been placed in them both collectively and individually by various public bodies such as general hospitals and infirmaries where so large a number of their members held appointments. Certain authorities, hospitals and other

institutions throughout the country had realised the importance of chiropodial treatment, and last year 120,000 treatments were given in the five foot hospitals with which the society was associated. But all these were merely touching the fringe of this vital problem. The only way of dealing adequately with this important question was to make chiropody available as a panel benefit under the National Health Insurance, thus giving 15,000,000 people the opportunity to improve their general physical condition.

Royal Society of Medicine

This society's house and library will be closed from Wednesday, May 12th, to Tuesday, May 18th, both days inclusive.

International Congress on Occupational Diseases and Industrial Welfare

The *Journées Internationales de Pathologie et d'Organisation du Travail* will be held in Paris from June 1st to 6th under the presidency of V. Balthazard, professor of forensic medicine in the University of Paris. Further information may be had from the secretary general of the congress, Dr. G. Hausser, *Institute Médico-Légal*, Place Mazas, Paris XII.

Travelling Fellowships in Medicine

The Medical Research Council invite applications for six Rockefeller medical fellowships for the academic year 1937-38. These are provided from a fund with which the council have been entrusted by the Rockefeller Foundation of New York. They are intended for British graduates who have had some training in research work in clinical medicine or surgery, or in some other branch of medical science, and who are likely to profit by a period of work at a centre in the United States or elsewhere abroad, before taking up positions for higher teaching or research in the United Kingdom. The stipend will ordinarily be at the rate of £400 per annum for a single fellow, and of £450 per annum for a married fellow. Travelling expenses and some other allowances will be paid in addition.

The Council also invite applications for four Dorothy Temple Cross research fellowships in tuberculosis. The object of these fellowships is to give special opportunities for study or research to suitably qualified British subjects of either sex "intending to devote themselves to the advancement by teaching or research of curative or preventive treatment of tuberculosis in all or any of its forms." The stipend will ordinarily be fixed at the rate of £400 per annum, with travelling expenses in addition.

Applications for these fellowships must be sent to the Council not later than June 1st. Further particulars may be had from the secretary of the Council, 38, Old Queen Street, London, S.W.1.

Fellowship of Medicine and Post-Graduate Medical Association

The following courses will be given during May and early June: dermatology at St. John's Hospital (afternoons, May 3rd to 29th), thoracic surgery at the Brompton Hospital (all-day, May 24th to 29th), urology at St. Peter's Hospital (all day, May 31st to June 12th), gynaecology at the Chelsea Hospital for Women (June 14th to 26th). Week-end courses will be held in chest diseases at the Brompton Hospital (May 8th and 9th), in physical medicine at the St. John Clinic and Institute of Physical Medicine (May 22nd and 23rd), in children's diseases at the Princess Elizabeth of York Hospital (May 29th and 30th), in general medicine at the Prince of Wales Hospital (June 5th and 6th), in obstetrics at the City of London Maternity Hospital (June 12th and 13th). During June, for M.R.C.P. candidates, there will be a clinical and pathological course at the National Temperance Hospital (8 P.M., Tuesdays and Thursdays, June 1st to 17th), a course in chest diseases at the Brompton Hospital (twice weekly, 5 P.M., June 7th to July 3rd), a course in heart and lung diseases at the Victoria Park Hospital (Wednesdays and Fridays, 6 P.M., June 9th to July 3rd) and an afternoon course in neurology at the West End Hospital for Nervous Diseases (June 21st to July 3rd). The annual dinner-dance of the fellowship will take place at Claridge's Hotel on Friday, May 28th, tickets can be obtained from the secretary of the fellowship at 1 Wimpole Street, London, W.1, by any member of the medical profession.

NOTES, COMMENTS, AND ABSTRACTS

THE MATERNAL MORTALITY REPORT

For two years medical officers of the Ministry of Health have been making a special investigation of maternal mortality and morbidity. Their long awaited report is published as we go to press.

The task before them was to discover why the puerperal mortality rate has not fallen despite increased interest taken in maternal welfare extension of maternity services and improvement in the general health.

FACTORS IN CAUSATION

Dealing with the regional distribution they point out that for many years puerperal mortality has been higher in Wales and the north west of England than in the country as a whole. This regional inequality is however not confined to maternal mortality rates with certain exceptions the distribution of the general death rates infant mortality rates tuberculosis and other rates show some correspondence with the rates from puerperal causes.

Various factors possibly responsible were considered. The available evidence shows it is reported that districts in which there are areas with *bad housing and overcrowding* are just as likely to have low rates of puerperal mortality as those in which the housing is good and the overcrowding less. In the districts visited it was not generally found that the puerperal mortality rates were higher in the areas with most overcrowding. Nor did these show any consistent association with corresponding variations in economic conditions. The influence of the nature of the diet and of nutrition on maternal mortality cannot it is observed, be accurately assessed in the present state of knowledge. The tendency for the mortality rates to be higher in the north and west and lower in the south and east of the country suggested that climatic conditions might in part exert an influence but the data required to demonstrate the association are not complete. Again it was found that deaths from puerperal sepsis tended to occur most frequently in the coldest quarter of the year that being the quarter which immediately succeeds the wettest and moistest quarter while deaths from toxæmia tend to occur in the warmest quarter. But the significance of this association cannot yet be assessed.

The information obtained by the investigators suggests that the practice of artificially induced abortion is frequent appears to be increasing is more prevalent in some districts than in others and is not restricted to any one social class. Approximately 14 per cent of all puerperal deaths are due to this cause (excluding deaths from abortion classed as criminal). The risk attending artificially induced abortion does not appear to be sufficiently realised and there is urgent need for the education of women respecting the damage to health and the danger to life from attempts to terminate pregnancy artificially. The facilities available in some areas for the in patient treatment of cases of abortion under expert supervision are inadequate.

THE MATERNITY SERVICE AND THE PRACTITIONER

Local investigation of maternal deaths indicates that ignorance or lack of co-operation on the part of the patient or her relatives often prejudiced her chance of recovery and illustrated the need for more systematic and careful medical supervision during the antenatal period more skilful management of some confinements more frequent reference of cases of doubt or difficulty for the advice and treatment of

an expert obstetrician and earlier admission to hospital of many patients. The primary conclusions of the investigators are that (1) those general practitioners who undertake obstetric work should be interested experienced and actively engaged in the practice of midwifery have sufficient time for unhurried work and be prepared to co-operate with the appropriate members of the local public health department and with the other agents concerned with the promotion of maternal welfare in the district. (2) The services of obstetric experts should be readily accessible in every area. (3) Everything possible should be done not only to induce expectant mothers to avail themselves of the facilities provided for them but also to impress upon them the importance of accepting and acting upon the advice proffered.

The report contains an outline of an efficient maternity service of a local authority and includes subjects recommended for consideration in order to render the services more fully effective. It is pointed out that the underlying principles of antenatal care are sound but that optimal results cannot be expected until antenatal supervision attains a high general standard and expectant mothers make full and intelligent use of it. The development of consultative antenatal clinic sessions under the clinical supervision of an expert obstetrician to serve every area is of importance in order to render antenatal services more efficient.

The report refers to the decrease in domiciliary confinements conducted by general practitioners the increase in those for which midwives are responsible and the rapid and increasing development of institutional midwifery in many districts. The investigation showed that many medical practitioners under take a considerable amount of obstetric work with competence and skill. The midwifery practice of some doctors has however decreased and the position in some towns is that unless a general practitioner has a special interest in midwifery or is of repute for his obstetric skill his maternity practice may be largely restricted to a few medical aid calls from midwives in the course of a year. The general practitioner is often called to an emergency in the patient's home and may have to cope without adequate assistance and in unfavourable surroundings, with critical situations which would challenge the skill of an obstetric specialist. Other calls upon his time may be pressing. Moreover the condition of the patient may be such as to compel him to take immediate action however disadvantageous the circumstances may be. The histories of many of the maternal deaths investigated indicated that notwithstanding these handicaps careful obstetric procedures were adopted but others showed that the woman's chance of recovery would often have been enhanced had a practitioner experienced in midwifery been in attendance had the doctor been assisted by an obstetric expert or had the patient been admitted to hospital sufficiently early.

The investigators consider that a doctor whose practice of midwifery is restricted to only a few cases each year cannot be expected to assist the midwife in difficulties which may urgently call for judgment and experience which in the circumstances he cannot be expected to possess. They suggest that the local supervising authority in consultation with the local medical profession should in future be empowered to take steps to ensure that the best local obstetric skill is made available in all cases.

in which midwives are required under the rules of the Central Midwives Board to call in a doctor. Reference is also made to the need for specialist advice, and facilities for in-patient treatment, after confinement.

Much stress is laid on the value of a service of obstetric consultants, and attention is drawn to the infrequency with which the consultant facilities were utilised in some areas where they had been provided. The provision of so-called emergency units or "flying squads" in connexion with a maternity department, under the direction of an expert obstetrician, should help to reduce maternal mortality.

In the opinion of the investigators it is essential to the success of a maternity scheme that there should be co-operation between all those concerned, and, although this was a satisfactory feature in a few of the areas visited, in others its importance had not been recognised. The time for independent individual effort, they believe, is past. All persons engaged in any branch of a maternity service should consider themselves to be members of a team working towards the goal of safer motherhood. It is in this way and this way alone that effective continuity of supervision and treatment can be secured.

While there are many factors which influence maternal mortality, it is clear at least, says the report, that it is capable of reduction, and of the factors known to influence it the most important from the point of view of remedial action is the standard of midwifery practice.

THE "BONCHORD" HEARING-AID

A NEW valve amplifier hearing aid has been submitted to us by Messrs Allen and Hanburys. The model examined, M V 36, is assembled in a neat case measuring $6 \times 3\frac{1}{2} \times 3$ inches, and employs two stages of amplification, a small 36-volt dry battery and a 2-volt chargeable accumulator. The microphone is of the immersed electrode type, and a volume control is incorporated in the switch, in addition an automatic volume control is provided, which ensures that the ear will not be damaged by accidental loud noises. Tone control is obtained by the use of earpieces of various impedance, or by the employment of electrical filters. The price is 16 guineas, which includes a spare accumulator. The dry battery is said to have a life of about three months, and the accumulator to give 25 hours' use before recharging. A larger and more powerful model, M V 52, is obtainable, with three valves, at a cost of 18 guineas. A piezo-electric crystal microphone can be fitted to either model at an additional cost of 2 guineas, this is practically free from background noise and is particularly suitable for sufferers from tinnitus and for cases of senile deafness. We think that this microphone will be advisable in most cases, as background noise is considerable in valve aids which are capable of a very high degree of amplification.

THE WHOLESOMENESS OF CANNED FOODS—A circular written by Mr H B Cronshaw, Ph D, entitled "The Wholesomeness of Canned Foods," has been issued under the auspices of the International Tin Research and Development Council. The pamphlet contains a brief account of the history of canning and describes the premises and processes used for the purpose. The safety of canned foods as regards both chemical and bacterial contamination is emphasised and a brief review is given of recent work on the effect of heat as applied in canning processes, and on the nutritive value of foods (including vitamins). The statements are moderate and accurate so far as the best British factories are concerned.

Births, Marriages, and Deaths

BIRTHS

CRAIG—On April 22nd at Fulbourn street E the wife of Dr Norman S Craig of a son
DUNLOP—On April 18th, at Tebbury Glos the wife of Dr J Leeper Dunlop of a daughter
JENKINS—On April 20th the wife of Dr R D Jenkins of Almondsbury of a son
LYLE—On April 16th the wife of Dr Eric Lyle Bromley of a son
PRICE—On April 21st, the wife of Roy Kemball Price M D, of Brighton of a daughter
REED—On April 10th at Batu Gajah, FMS the wife of Dr J G Reed of a son
SMALLSHAW—On April 20th at Epsom Downs, the wife of Dr D B Smallshaw of a son
STEWART—On April 17th at Edinburgh the wife of Dr James Stewart 33 Hutton place Edinburgh of a daughter
THWAITES—On April 20th, at Caterham the wife of Dr P Thwaites, of Whyteleafe of a daughter

MARRIAGES

LANCASHIRE—GOODFELLOW—On April 17th at Bermuda Roger William George Lancashire Surg Lt R N to Christina Sophia, daughter of Dr and Mrs T A Goodfellow, West Didsbury Manchester
MACLEAN—LOVE—On April 15th, at Burton-on-Trent Nell MacIntosh MacLean M B Glasg of Doncaster to Gwyneth Duncan Love M B Edin, of Tunbridge Wells
SAVILLE PECK—JOHNSON—On April 20th at Madingley Cambridge, John Portway Saville Peck M B Camb, to Nora Eugene, daughter of the Rev M Johnson, of Farway Devon
WHITEHEAD—CHAPMAN—On April 8th, 1937, at St Paul's Church, Mill Hill James Edward, son of the late John Kay Whitehead of Royston Lanes, and Mrs Whitehead to Marjorie Beatrice, younger daughter of Charles W Chapman, M D, M R C P and Mrs Chapman of Highwood Coombe, Mill Hill N W 7

DEATHS

ANDERSON—On April 19th at Erdington Birmingham Robert Anderson B Chir Camb, Captain R A M C (T), aged 33
HAIG—On April 22nd, at Woking, Francis Murray Haig M D Camb
HINE—On April 26th at Slapton, Devon, Thomas Guy Macaulay Hine O B E, M A, M D Camb, Hon Major R A M C aged 66
HUNTER—On April 18th at Haughley, Suffolk G H Hunter M R C S D P H aged 79
MUDD—On April 21st at Illovo Johannesburg Frank Burnard Mudd, M R C S, younger son of the late Dr Barrington R Mudd, of Storrington Sussex
PHILIP—On the 23rd April at 45, Charlotte square Edinburgh Elizabeth wife of Sir Robert Philip M D, F R C P (Please no flowers)
WALDY—On April 25th at Darlington C Durham, John Waldy F R C S Eng aged 76
WIDDUP—On April 23rd at Southsea the home of his daughter (Mrs Nora Blackwood) John Charles Ponsonby Widdup late Colonial Medical Service
YARR—On April 24th in London Major General Sir (Michael) Thomas Yarr K C M G C B, late R A M C, of Queen Anne's Mansions St James's

N B—A fee of 7s 6d is charged for the insertion of Notices of Births Marriages and Deaths

UNWANTED INDICES to "THE LANCET"—Any reader who has an unbound copy not in use of the index for 1935 (Vol I) and 1936 (Vol I) would greatly oblige by posting the same to the Editor of THE LANCET, 7, Adam street, Adelphi, London, W C 2

ST BARTHOLOMEW'S HOSPITAL—Overseas visitors are to be given the opportunity of "viewing" the old Priory Church and ancient hospital of St Bartholomew's. Conducted tours have been arranged from May 7th to 14th (excluding Sunday and Coronation Day) at 11 A M and 2.30 P M each day. There will also be an exhibition in the great hall of the treasures of the hospital of drugs obtained from the Empire, a collection of historical pathological specimens and many first editions of well known medical works. The exhibition will be open from 11 A M to 5.30 P M daily. There will be short talks on the Hogarth painting at 4.30 each afternoon. Further information may be had from the hospital.

ADDRESSES AND ORIGINAL ARTICLES

THE PREVENTION OF PULMONARY TUBERCULOSIS AMONG ADULTS IN ENGLAND IN THE PAST AND IN THE FUTURE*

By P. M. D. ARCY HART, M.D. Camb. F.R.C.P. Lond.

ASSISTANT PHYSICIAN TO UNIVERSITY COLLEGE
HOSPITAL, LONDON

(Concluded from p. 1025)

At the beginning of these lectures I adopted a wide use of the term prevention as applied to pulmonary tuberculosis and included within it the prevention of further advance of progressive lesions after their presence has been recognised. The likelihood of this being achieved in a particular instance is intimately connected with the prognosis of the case. One of the objects of the anti-tuberculosis measures embodied in the national tuberculosis scheme has been to improve this prognosis.

The ratios of new cases to deaths published annually by the Ministry of Health (e.g. 1935a) give a rough indication of changes in the average prognosis of diagnosed cases of pulmonary tuberculosis over the past two decades and so enable us to judge approximately the success of this endeavour. Unfortunately these ratios actually decreased between 1913 and 1922 and changed but little between 1923 and 1935 these being comparable years. While a number of minor factors affect their significance, it would be difficult in view of their failure to increase to assert that average prognosis has improved materially. In other words a decline in incidence of new cases rather than an improvement in their prognosis appears to have been mainly responsible for the decline in mortality. This view is supported by the conclusions of Hartley Wingfield and Burrows (1935) based on the records of the Brompton Hospital Sanatorium. Frimley that the prognosis of an average case of pulmonary tuberculosis has not materially changed during the past thirty years though that of a small selected class treated by collapse therapy has considerably improved.

It follows that unless we are to rely upon general social improvements and protection from contacts to continue the reduction in incidence of pulmonary tuberculosis we shall be faced with the serious problem of how to improve the prognosis. Such improvement might be achieved by earlier diagnosis, better treatment and better after-care—the last of these having already been discussed.

EARLIER DIAGNOSIS AS A MEANS OF IMPROVING PROGNOSIS

That there is room for earlier diagnosis is generally agreed.

Of 32,000 patients discharged from or dying in, approved residential institutions in England and Wales during the year 1935-36 per cent were classified at the time of admission as belonging to Class *T B* plus Groups 2 or 3 (intermediate or advanced); this figure if anything underestimates the position since Class *T B* minus is not also subdivided into groups. The total number of Class *T B* plus cases was 23,000, all of which must have been infective and diagnosable for an unknown period and of these only 12 per cent were classified in Group 1 (early or

slight) the remaining 88 per cent being already in an intermediate or advanced stage (Ministry of Health 1936 1935d).

It is also believed that an increase in the proportion of persons diagnosed in the slight or early stages would be of great benefit. This view is founded upon two pieces of evidence. One is that recognition and treatment is an actual advantage. This may appear obvious from clinical experience but its statistical demonstration is not easy (see MacNalty 1932c) and has only lately been achieved with any degree of certainty (Hartley Wingfield and Burrows 1935). The other piece of evidence is that whatever the particular form of treatment the prognosis is closely related to the extent of lung involvement at the time of diagnosis.

Thus Trail and Stockman (1931) in their follow up of patients of Mithurst sanatorium found that the survival rate of early sputum positive cases five years after admission was twice that of advanced cases. In his analysis of the ultimate results of sanatorium treatment MacNalty (1932b) concludes that a patient's chance of survival is enormously increased in proportion as he is admitted to sanatorium treatment in the early stage of his disease. The London County Council (e.g. 1933b) consistently reports similar findings as to survival and fitness for work among its patients five years after residential treatment. Bentley (1935b) in his analysis of the pneumothorax cases of the L.C.C. since 1922, stresses the greater likelihood of finding unilateral disease and obtaining complete collapse (on which two factors prognosis largely depends) where the disease has not progressed for long. And Hartley Wingfield and Burrows (1935) in their study of the after histories of Frimley patients conclude that the mortality in their series depended almost entirely upon the classified stage of the disease at the time of entry and was relatively unaffected by sex or age while the finding of a strong relationship between radiographic extent of the disease and the prognosis provided similar evidence from a different angle.

The apparent lack of improvement in average prognosis in the past twenty or thirty years together with the fact that prognosis is related to the stage at which the disease is recognised suggests that the proportion of cases diagnosed in the slighter or earlier stages has not materially increased during this period. Direct comparison is difficult because of changes in personnel and point of view but the following figures are of interest.

They are obtained from a county whose local tuberculosis scheme is unsurpassed in efficiency and for better comparison the analysis is confined to sputum-positive cases. In the triennium 1920-28 there were 294 new sputum positive cases and in the triennium 1933-35 this total was 2234. The percentage of these cases classified as belonging to Group 1 and Group 3 respectively was 13.5 and 27 in the earlier triennium and 12 and 21 in the later triennium (Lancashire 1927 1928 1933 1934 1935a).

While the interval is short these figures taken at their face-value show little sign of earlier diagnosis under the best conditions of present practice.

It is clear therefore that diagnosis remains unsatisfactorily late and that every effort should be made to advance it so as to improve prognosis.

BETTER TREATMENT AS A MEAN OF IMPROVING PROGNOSIS

The extent to which modern methods of treatment improve prognosis may be gauged from recent

* A similar lack of increase in the proportion diagnosed as minimal tuberculosis (American Association of Tuberculosis 1935) for the clinics operated by the health department of New York City during 1933-36 (Edwards 1937).

reports from institutions, including Midhurst sanatorium (Trail and Stockman 1932, Trail 1934), Frimley sanatorium (Hartley, Wingfield, and Burrows 1935), and the LCC sanatoria (Bentley 1936b). It appears that the proportion of cases found suitable for pneumothorax treatment is relatively small (10 per cent in the LCC service). The chance of survival in all cases undertaken, considered together, is materially improved (by 20 per cent at five years, in the LCC series) by such treatment, the best results being obtained in those whose lesions are strictly unilateral and in which complete collapse is secured (accounting only for a quarter of the LCC cases undertaken). This suggests that pneumothorax treatment has improved prognosis in a small selected category of cases, though it has not yet made a significant impression on the prognosis of the average tuberculous case. In the future the technique of other methods of collapse will probably improve and their range will widen, but this is less obviously likely with pneumothorax treatment. Its effect on average prognosis is likely to remain small and limited (4 per cent increased chance of survival at five years, according to Bentley's estimate), *unless the proportion of suitable cases increases*. Since suitable cases and slight or early cases are in the main synonymous, the future usefulness of pneumothorax treatment on tuberculous patients *as a whole* appears to turn on more frequent diagnosis in the early stages. Such earlier diagnosis would be doubly useful since it should also help to eliminate potential or actual sources of infection for others.

Methods of Obtaining Early Diagnosis in the Past

What methods have been used to obtain early diagnosis? Why have they been a comparative failure? Is extension of these older methods, or the introduction of fresh ones, desirable to ensure better success?

CONSULTANT SERVICE

Until recently it was usual to date the onset of tuberculous disease in adults from the appearance of symptoms or physical signs. The consultant service of the dispensary system of the national tuberculosis scheme was based on this conception. To the patient has been left the initiative of obtaining the first medical interview. A "case" of pulmonary tuberculosis has therefore meant a case with symptoms or physical signs as well as radiographic abnormalities, and attempts at earlier diagnosis have been directed to shortening the interval between the development of symptoms that attracts the attention of the patient, and the recognition of progressive lesions.

Delay in diagnosis after the appearance of symptoms—For purposes of discussion the interval between symptoms and diagnosis can be divided into two parts. (1) the patient has symptoms but has not yet sought medical advice, (2) he is under medical observation but his condition has not yet been diagnosed as pulmonary tuberculosis.

A common reason for delay in seeking medical advice is the hope of recovery without recourse to the doctor. Self-deception may be another reason, or personal courage, or the stigma attaching to the label of tuberculosis, may prevent him giving in. Other important causes for delay are economic. Chief among these are the knowledge that a long period of sickness probably means a reduced family income, and possibly unemployment afterwards—factors that may prevent the patient consulting his doctor until he is incapacitated for work.

If the duration of symptoms before first medical interview is variable, so also is the period between the interview and the diagnosis. Burton Fanning (1934) states that in one series of tuberculous patients there was undue delay by the patient in 20 per cent of cases, and by the doctor in 7—not coextensive—25 per cent. In another series (different investigator and criteria), the corresponding percentages were 20 and 35. These figures may give a crude indication of responsibility, but they are of more interest perhaps in suggesting that in the majority of cases there is no undue delay in diagnosis from the onset of *really definite* symptoms. The difficulty is that the first symptoms are often quite indefinite.

Efforts to reduce this delay—While patients are left to decide whether they require treatment it is by no means easy to shorten the interval between symptoms and diagnosis. One method used for the purpose is publicity. "A larger number of persons who may be suffering from tuberculosis must be persuaded to submit themselves for examination" (Ministry of Health 1933). "The initiative to seek treatment when ill rests with the patient himself, and the only feasible remedy (for delay) lies in the education of the public as to symptoms and common dangers of tuberculosis and the need for securing prompt treatment" (Lancashire 1935c). Informative pamphlets have been issued by local health authorities and by the National Association for Prevention of Tuberculosis. For the family doctor, closer co-operation between the dispensary physician and himself has been secured, while he has been given the right to free sputum examination without intermediary. Since, in the country as a whole, there is little evidence on whether the interval between symptoms and diagnosis has been reduced in the past fifteen years, it is difficult to judge the effect of these specifically planned efforts. However, from the figures already given, it seems clear that even if diagnosis is now somewhat earlier in time it is not yet sufficiently early in stage. Two explanations of this comparative failure may be suggested.

One is that the planned efforts have not been adequately exploited—that enough has not been done to counter the economic factors that deter the patient from seeking advice, and that attempts to educate the public have not been sufficiently bold. Perhaps caution in the use of public instruction is partly due to anxiety lest "disease consciousness" or hypochondriasis be created in the nation (see Hutchison 1934). Again, while the family doctor has been given direct access to sputum examination, the even more important privilege of direct free radiographic chest examination and report has not yet been granted, and in the absence of this privilege intensive propaganda might burden hospitals with a large influx of unwanted out patients.

The other possible explanation for the failure is that the attempt to secure sufficiently early diagnosis *solely* by efforts to shorten the interval between symptoms and diagnosis is unsound, being based upon an outmoded conception of the evolution of pulmonary tuberculosis. It is nowadays supposed that the first stage of the process is pulmonary first infection discoverable by the tuberculin test and sometimes also radiographically. After a short or long interval progressive pulmonary lesions develop, which are often detectable with X rays for some considerable time before they give rise to significant symptoms or physical signs, though indefinite or insidious symptoms may be present at this stage. During this asymptomatic (latent, preclinical) stage progressive lesions are, therefore, recognisable as such

by radiograph but in no other way. They may be slight in extent, on the other hand they may develop beyond the size that corresponds to the Ministry of Health Group 1 classification before they lead to definite symptoms. When significant symptoms do develop they may be toxic or local or both. In this the so-called clinical or manifest stage the presence of progressive lesions is discoverable clinically radiographically and possibly bacteriologically. However while tubercle bacilli in the sputum with their implication of infectiousness may be found early in this stage they must be regarded as heralding, a comparatively late and dangerous phase when the whole course of the disease is taken into consideration.

The view differs from the older conception, which has dominated the methods of tuberculosis dispensary consultant practice, chiefly in emphasising the asymptomatic stage of progressive lesions and by laying the onset of disease from the first appearance of these lesions and not from development of the symptoms. The deduction is that efforts such as those already undertaken under the national tuberculosis scheme to shorten the interval between the onset of significant symptoms and the making of the diagnosis cannot be expected by themselves to secure diagnosis at a time when the lesions are slight non-infectious and usually susceptible to treatment. In expanded form and in conjunction with different methods however they should be of considerable use. On the other hand attempts to recognise progressive tuberculosis from early but indefinite symptoms such as slight general unfitness are more likely to confuse than to assist.

Methods of Obtaining Early Diagnosis in the Future

PERIODIC MEDICAL EXAMINATION

What is required therefore is a procedure whereby progressive lesions may be discovered in the asymptomatic or preclinical stage and as early as possible in their development. This must involve the periodic X-ray examination of persons supposed to be in good health. The length of the intervals between such examinations will be determined by the person's history by the risk likely to be run and by the presence of any suspicious X-ray shadows or symptoms.

Such a method is essentially dynamic for its aim is to detect changes—of progression and regression—and not merely to ascertain statically the extent and character of a lesion at a particular time. For this purpose it is well to secure if possible at least one negative examination to serve as the individual's base-line; hence the first examination should be carried out when he is likely to be in actual as well as in supposed health.

For economy of effort the unit for investigation would best be a group of persons who are normally associated together and therefore easily accessible—e.g. students of a college or workers in a factory—rather than isolated and independent individuals. Since it affords a reasonable chance of detecting the pulmonary lesions before symptoms arise and of forming a precise opinion as to the progressive nature of these lesions when detected routine periodic examination should secure improved results from treatment and greater safety for the local community. If lesions develop between the periodic examinations the initiative will of course rest as at present with the patient but with the established routine of medical examination the provision of the medical

service on the spot, and the warning to report particular complaints he might be expected to take this initiative sooner than in ordinary practice. In any event a limit is set to the delay and whether the disease is detected before or at the next routine examination the advantage of serial radiograms in helping to form an opinion will still apply.

Since it involves regular examination while in health and since it takes the main initiative of medical interview away from the patient and gives it to the doctor this method of obtaining early diagnosis rests upon a principle that differs profoundly from that underlying the patient family doctor specialist relationship of the greater part of medical practice. But it is of course no new principle for it has been adopted by many departments of the voluntary and municipal hospital and public health services—e.g. in child welfare and antenatal clinics in school medical and dental inspection—as well as by many dental surgeons in private practice.

THE PRESENT CONTACT EXAMINATION SERVICE OF THE TUBERCULOSIS DISPENSARY SYSTEM

At the time of its introduction the national tuberculosis scheme could not have included routine periodic examination as a part of the functions of its consultant dispensary service but an important step was taken in establishing the service for examination of contacts. This is, of course, no more than a step in the right direction. Since the first examination of a contact cannot be made until at least one case has been discovered in the household—and in nearly 10 per cent this discovery is not made until there has been a death—it is often made too late to prevent the disease from spreading. And since for the same reason first examination of a contact takes place at a time when already he has a more than average chance of having a progressive lesion the scheme may well fall in its intention to detect disease in its early stages.

Other limitations of the present contacts scheme lie in its execution. The proportion of home contacts examined as such is increasing; thus in London in 1931 the ratio of new contacts (adults and children) examined to new cases of tuberculosis taken on the dispensary registers was 1.8 to 1 (Bentley 1936c). But for the country as a whole in that year the ratio was only 1.2 to 1 (Ministry of Health 1935a) and taking the 1931 census figure of 3.72 as the average number of persons per family in England and Wales this represents slightly less than half the possible home contacts.

Again while in some dispensaries all adult contacts are re-radiographed on first examination in others this is only done if suspicious symptoms or signs be present—and while in some dispensaries the adult contact more particularly the young adult contact who is found normal on first examination is invited to return at regular intervals for re-examination so long as exposure continues and for some years afterwards, in others he is only instructed to return should he feel ill or alarmed. Even when close observation of apparently healthy young adult home contacts is being maintained many local authorities would consider themselves unable to carry the expense of including serial radiograms in such periodic examination. If all new contacts (adult and child) of all new cases of tuberculosis in the London dispensary area were to be radiographed once a year for five years and if the incidence of new cases were to remain at their present figure then according to a rough estimate made by Bentley (1936c) over 60,000 radiograms of home contacts (and if limited to contacts of sputum positive cases) would have to be taken and read annually in that area.

Finally it should be noted that the examination of contacts (child and adult) accounted for 8.7 per cent of the total number of cases of tuberculosis (discharge) in the dispensary service in 1931. (Ministry of Health 1931)

In assessing this result however, this figure of 8 per cent may be compared with Lloyd and MacPherson's (1936) finding that 30 per cent of their series of young adult cases of pulmonary tuberculosis gave a history of contact in the home, and therefore could presumably themselves have been located by a follow up of the family of the earlier case. The comparison is crude, since the material has a different age constitution, but it is nevertheless of some interest.

Although in its present form the examination of contacts under the tuberculosis scheme cannot be regarded as more than a partially developed example of periodic examination of adults in supposed health, the experience gained would be of immense value should any further step be contemplated. Whether the present service is likely to be expanded and modified, or to be eventually superseded, is a question that will be discussed later.

EXAMPLES OF SCHEMES OF PERIODIC EXAMINATION

During the past few years a number of group schemes of periodic examination of supposedly healthy persons for tuberculosis have been introduced, especially in the United States. So far the majority of them have been applied to groups of young adults, more particularly those who run a greater than average risk of exposure to open tuberculosis. For this category of persons, such schemes probably constitute the best means of observation, especially if combined with Mantoux testing, which—whatever its other implications—should exclude the presence of tuberculous infection in some of them (see Hart 1932, 1937). The selected groups have included medical students (Hetherington, McPhedran, Landis, and Opie 1931, 1935), medical and other university students (Soper and Wilson 1935, Diehl and Myers 1936), and hospital nurses. In most of the schemes the standard interval between routine examinations has been a year, but the prescribed interval is of course reduced in individual cases when indicated.

At the first examination after the introduction of a scheme, a number of persons in presumed health have usually been discovered to have serious and open lesions. In one large university hospital in America these included the sister in charge of the labour ward, and also a nurse working in the operating theatre. On the other hand (Downes 1934, Barnard 1934), the number of cases with severe lesions (Stage 2 or 3), expressed as a percentage of total active cases found, tends, as would be expected, to be smaller than in a series of tuberculous cases diagnosed in the ordinary way. While the immediate discoveries usually provide immediate justification for the scheme as a method of case finding, it is only after it has been in operation for some little time that its full benefits are experienced, with a further fall in the incidence of severe lesions among the active cases discovered.

Periodic examination of employees—The scheme that has attracted most attention is one that does not come into the category of examination of young adults exposed to exceptional risks of contact, but applies to adults of various ages under ordinary conditions of work. It has been in operation since 1928, under the direction of Dr H. H. Fellows and his associates, among the 13,000 employee population of the New York office of the Metropolitan Life Insurance Co., a mutual company with no stockholders.

Before the introduction of this scheme all employees had a complete physical examination once a year, but a chest radiogram was taken only if suspicious symptoms or signs were elicited. Now, however, in addition to their physical overhaul they have an annual screening, followed by a film if thought desirable. For those with doubtful lesions the interval is deliberately shortened, and all employees are asked to report during intermediate periods

if symptoms should appear. Persons discovered to have significant active lesions are kept under close supervision or are advised, though not compelled, to have sanatorium treatment, the latter can, if desired, be given at the company's own sanatorium so that the scheme is self-contained. These persons return to work after treatment as soon as they are considered fit.

The success of this scheme can be judged from the following details (The difference between the American and English classifications must be borne in mind, in particular the American subdivision of *T.B. minus* as well as of *T.B. plus* cases into three groups).

A total of 201 new cases with significant active lesions requiring treatment occurred between 1929 and 1935 among employees, the incidence per 10,000 employee population being 28 in 1929, 23 in 1930, thereafter remaining between 19 and 24 (except for 1933 when it was 14). The incidence, per 10,000 employee population, of new active cases found in Stage 2 or 3 (moderately or far advanced) fell from 21 in 1929 (already a year after the scheme had commenced) and 15 in 1930 to 12 in 1931, 7 in 1932 and 1933, 6 in 1934, and 9 in 1935, while the number of new active cases found in Stage 1 (minimal), expressed as a percentage of the total new active cases, rose from 31 in 1929–30 to 62 in 1932–33 and 1934–35.

A series of 141 active cases admitted to the company's sanatorium was analysed in especial detail. In the majority the disease had been detected before they were ill in the ordinary sense, and before physical signs were present. One third had no symptoms at the time of diagnosis, over half had not lost weight during the previous year, and only 13 per cent admitted to having a cough. Half were discovered at a routine examination, and the other half as a result of seeking advice for symptoms in an interval period. Thirty-one per cent of the cases were *T.B. plus* at some time during treatment. The percentage of the whole group detected in Stage 1 (minimal) was 65, which was stated to be five times the average admission rate for minimal cases among United States sanatoria in general. Of those discovered as a result of symptoms, 60 per cent were in Stage 1, for those discovered at routine examination the percentage was 69, while for those with no symptoms at the time of diagnosis it was as high as 79. Of the sputum positive cases however—one third of which were cases that had been diagnosed at a routine examination—only 27 per cent were in Stage 1 and 12 per cent were actually in Stage 3 (Fellows 1934a, 1934b, 1935, Reid 1933, 1934, 1935, Barnard 1934).

While it is too early to know the ultimate results of treatment of the active cases discovered by this scheme, it seems to have justified the hope of recognizing lesions at an earlier stage than before. One would expect even better results if a film as well as, or instead of, screening were made at each routine examination, so as to give a permanent record for comparison.

SCHEME FOR STUDENTS OF UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL

In 1935, having regard to the gathering movement in favour of student health services in this country, to the predominance of pulmonary tuberculosis among the incapacitating diseases of young adults, and to the retardation in decline of mortality from this disease at this age in recent years, the medical school committee of University College Hospital instituted a scheme of periodic medical examination of students occupied in clinical training or in qualified house appointments (The examination, at present limited to the detection of pulmonary tuberculosis, may form part of a more comprehensive health service to be introduced later). The scheme was placed under the charge of Mrs. Gwen Hilton as radiologist, and of myself as physician, and has now been in operation for a year. Since it is apparently the first of its kind in this country, I will describe the administrative

routine in some detail (with permission of the dean), in the hope that it may assist others contemplating a similar service.

All but 4 of 300 eligible and accessible students have entered the scheme which is essentially voluntary. The information is treated as confidential, and any student found to have doubtful or definite progressive lesions is referred to the doctor of his choice for further opinion or advice. While he is not required to take the advice given, it is not anticipated that the problem of a serious or sputum positive case refusing treatment is likely to arise. The service is free but no provision is made for the cost of treatment.

An explanatory leaflet is issued to each student before his first examination. The latter consists of screening and film of the chest and the student answers a questionnaire concerning his family and past and present medical history as regards respiratory disease. Discussion between radiologist and physician is followed a few days later by an interview between the physician and the student at which the weight is recorded, the history completed and physical or sputum examination made if the history or radiogram indicates it. At this interview the result of the whole examination is given to the student any special action to be taken is decided upon and the date for the next routine examination fixed.

The standard interval between routine examinations is at present one year but this interval is shortened either at the will of the doctors if the history or radiogram of the previous examination suggests the advisability of closer observation or at the will of the student if suspicious symptoms develop. The student is particularly asked to seek advice during the period between routine examinations should he become worried about his chest, and it is hoped that the items on the questionnaire together with his medical training will enable him to recognise symptoms requiring an intermediate re-examination and that the established routine and convenient situation of the medical service will encourage him to take the initiative to obtain it.

Re-examinations are similar to the first examination, though screening is usually omitted. The chest film is taken under conditions so far as possible comparable with those used on the first occasion. At the clinical interview the weight record and medical history are brought up to date.

Already this scheme has revealed several persons with undoubtedly progressive though comparatively slight and favourable lesions requiring treatment. These lesions were discovered at routine examination were unaccompanied by definitely significant symptoms and would not have been detected until later without such a scheme. The number of such cases however was considered no more than would be expected in a medical student population.

It is hoped that within a few years the University College Hospital and any similar schemes will have demonstrated the practical possibilities and value of this type of health service for young adults and may justify their introduction on a large scale. By that time some of the results of the Prophit scheme of the Royal College of Physicians concerning the evolution of the types of pulmonary lesion likely to be met and their relation both to Mantoux sensitivity should be available. Besides serving as one possible model the present scheme should throw light on the significance of the common respiratory symptoms in a student population.

OBJECTIONS AND DIFFICULTIES

Since the adaptation of the tuberculosis services so as to allow of periodic examination is envisaged as a possibility of the near future both in the United States (Kiernan 1936) and in England (Trail 1936 Wingfield and MacPherson 1934) it is worth considering some of the objection likely to be raised and difficulties likely to be encountered.
